1.0 INTRODUCTION

This Appendix provides a habitat assessment analysis of alternatives proposed for the Los Angeles (LA) River Ecosystem Restoration (ER) Feasibility Study (the “Study”), Los Angeles, California. The Study examines restoration opportunities within an 11-mile segment of the LA River, referred to as the ARBOR (Alternative with Restoration Benefits and Opportunities for Revitalization) reach (hereafter referred to as Study area) (Figure 1-1). The Study alternatives evaluate restoration of the area to a condition characteristic of the historic, natural riparian river channel, as limited by the surrounding highly urbanized City of LA and the channel’s purpose for flood risk management. Development of restoration alternatives was based on the following study objectives:

- Restore Valley Foothill Riparian Strand and Freshwater Marsh Habitat.
- Increase Habitat Connectivity.

2.0 STUDY BACKGROUND

The U.S. Army Corps of Engineers’ (Corps’) involvement with the LA River began in the 1930s after devastating floods destroyed homes, businesses, and infrastructure in the early 20th Century. The City of Los Angeles and Los Angeles County initiated the flood control program that channelized the river after these floods. Congress authorized the Corps to undertake, with the County as partner, a modified version of the County’s comprehensive plan. The Corps then joined the efforts, which led to the further channelization of the River in the 1930s and 1940s and the current concrete configuration. This configuration drastically altered the remaining riparian and freshwater marsh habitats as well as ecosystem functions in the once natural River system. The flood risk management project also allowed for increased urbanization and development in the floodplain, further reducing the marsh and riparian habitats that had naturally occurred on the river and its tributaries. The Corps’ involvement on the LA River continues today in sharing operation and maintenance responsibilities with the LA County Flood Control District. The Corps has operation and maintenance responsibility for the portion of the river within the Study Area.

The U.S. Congress directed the Corps to undertake the LA River Ecosystem Restoration Study in 2006. The Study initially focused on the first 32 miles of river, and was subsequently narrowed to focus on the 11.5-mile Study area (aka ARBOR reach), which exhibits the greatest potential for ecosystem restoration. This reach includes the “soft-bottomed” Glendale Narrows that connects Griffith Park to Downtown LA and that currently supports degraded riparian habitat. The soft-bottomed reaches currently support a natural bed with concrete banks due to a high groundwater table that did not allow the bed to be constructed with concrete.

In 2007, the City of LA adopted the long-range LA River Revitalization Master Plan that calls for the creation of a 64-mile network of trails, parks, and recreation along both sides of the first 32 miles of the LA River, from the San Fernando Valley to the City of LA’s border with the City of Vernon, an area home to more than one million people. The entire Study area is within the Master Plan’s focus area.

Figure 1-1. ARBOR Study Area

The Feasibility Scoping Meeting milestone¹ for the LA River ER Study occurred in November 2007. The Study is currently in the Plan Formulation and Evaluation Phase with the City of LA as the non-Federal local sponsor. Planning workshops were held in December 2009, and the Corps used the information from these workshops to develop 19 preliminary alternatives defined by combinations of more than 200 measures. Elements from these preliminary 19 alternatives were later recombined and eventually reduced to four final alternatives for detailed consideration based on preliminary design and cost-benefit analyses. A final recommended plan will be chosen from this group of four alternatives.

3.0 SITE DESCRIPTION

The 11-mile Study area encompasses the soft bottom Glendale Narrows as well as portions of the concrete channel from Griffith Park to northern downtown LA. The Study area includes the LA River channel and select adjacent areas, beginning upstream at Pollywog Park, across from the Forest Lawn Cemetery. Further downstream, Verdugo Wash enters the LA River from the east, and the River then flows south through the Glendale Narrows. Just downstream of the Glendale Narrows, the Arroyo Seco enters the River from the east, and the River continues to flow south into downtown. The project area ends in downtown at First Street.

Large (i.e. in acreage) River-adjacent areas considered in the Study area include Pollywog Park, Burbank-Western Channel confluence, Bette Davis Park, Ferraro Fields, Verdugo Wash confluence, Griffith Park Golf Course (a.k.a. Harding Municipal Golf Course), Los Feliz Golf Course, Bowtie Parcel, Taylor Yard (a.k.a. G-2 Parcel), Arroyo Seco confluence, Cornfields (a.k.a. Los Angeles State Historic Park), and Piggyback Yard (Figure 3-1). The Study area encompasses approximately 842 acres.

The Study area is split into eight geomorphic reaches (Figure 3-2) generally defined by Study landmarks as follows:

- 1) Pollywog Park to Bette Davis Park (concrete bottom)
- 2) Bette Davis Park to Ferraro Fields (soft bottom)
- 3) Ferraro Fields to upstream Glendale Narrows (concrete bottom)
- 4) Upstream Glendale Narrows to Los Feliz Boulevard (soft bottom)
- 5) Los Feliz Boulevard to Bowtie Parcel (soft bottom)
- 6) Bowtie Parcel to downstream Glendale Narrows/Arroyo Seco (soft bottom)
- 7) Downstream Glendale Narrows/Arroyo Seco to Main Street (concrete bottom)
- 8) Main Street to First Street (concrete bottom)

*Note that all reaches have concrete banks

1 Feasibility Scoping Meeting (FSM) = The purpose of the FSM is to bring the Corps vertical management team, the non-Federal sponsor, and resource agencies together to agree on the problems and solutions to be investigated by a Study, and the scope of analyses required. An FSM will address the problems, opportunities, and needs; refine study constraints; identify the key alternatives; and further define the scope, depth, and methods of analyses required.

Figure 3-1. Key River Adjacent Areas

Figure 3-2. Geomorphic Reaches

The reaches of the River with a concrete bottom have three configurations in the Study area, including box and trapezoidal, or a combination of the two. The “soft” bottom areas have predominantly rock and cobble substrate that support riparian and wetland vegetation within trapezoidal concrete slopes.

4.0 STUDY AND METHODOLOGY ASSUMPTIONS AND CONSTRAINTS

Due to its highly urbanized setting and the hydrologic alterations that the River has undergone prior to and since its channelization, there are several constraints that were considered in defining alternatives and assessing how these alternatives can achieve the Study objectives.

Historic hydrologic conditions that are extremely important to riverine, riparian, and marsh ecosystems have been irreversibly altered along most of the LA River. Complete restoration of historic conditions is not feasible; therefore, to the greatest extent possible, the Study aims to restore riparian and wetland vegetation communities and habitats that were known to occur historically.

Residential, commercial, and industrial land uses border the River, thereby limiting the area adjacent to the River available for restoration. This is an important determinant in the potential acreage of each community type in the habitat analysis. More importantly, it influences the spatial and structural diversity that can be attained, as well as the quality of riparian habitat in terms of characteristics such as availability of water to River adjacent restoration areas and the relationship between interior versus edge space. Presently, the Study area (i.e., width of the restoration corridor) has been predominantly defined by existing easements and rights of way, existing structures, availability of adjacent lands for acquisition, local topography, and the historic floodplain. Furthermore, several of the River-adjacent areas that would provide substantial lands for restoration, if acquired, require cleanup of hazardous and toxic wastes from previous uses, such as rail yards.

Overall, water availability in the project area during the non-flood season, is predominated by upstream releases from the Tillman Water Reclamation Plant, as well as local surface runoff. Ongoing water conservation efforts include holding more water at upstream reservoirs with the intent of percolating in spreading basins. The City also has plans to remove dry weather flows from the River as part of its Integrated Regional Plan, specifically the Department of Water and Power’s Recycled Water Master Plan. Lack of a more significant, reliable water source for the Study area poses constraints on the ability to sustain important functions of stream, riparian, and wetland habitats that currently exist, as well as proposed habitats in the alternative plans. However, the City is committed to maintaining flows necessary for the restoration plan to be implemented as a result of this study.

Several other ecosystem restoration studies and projects are on-going on LA River tributaries, including the Headworks, Sun Valley, and Arroyo Seco Ecosystem Restoration Continuing Authority Program Studies, and the Tujunga Wash project was recently completed. These Studies and projects will positively affect the LA River riverine system by restoring upstream habitat and functions, and by increasing ecosystem value. However, the implementation of these projects will also require a portion of the scarce water resources to support the restoration efforts.

The California High Speed Train (HST) project is also a factor in the extent to which the riparian ecosystem can be restored and the success of the restoration project in achieving its goals. Certain proposed alignment alternatives near the Study area may impact the restoration project. While HST project implementation is considered long-term and not precisely defined at this point, the alignments that abut and cross the Study area would have a negative impact on the value of wildlife habitat. Other development, transportation, and infrastructure projects occurring within or adjacent to the Study area would generally have a negative effect on restoration.

Ultimately the LA River in its current state is a flood risk management structure. The purpose of flood risk management must be maintained and there can be no increase in flood risk, thereby limiting the amount vegetation that can be sustained in the channel. Acquisition of river adjacent areas that would allow for widening of the River would allow for more vegetation in the channel; however these opportunities are limited.

Despite these constraints and limitations, the ARBOR reach retains the potential for substantial improvements to habitat quality in highly degraded areas, providing or enhancing wildlife movement corridors, and increasing nesting opportunities for native resident and migratory species.

5.0 HABITAT EVALUATION: COMBINED HABITAT ASSESSMENT PROTOCOL (CHAP)

5.1 CORPS RESTORATION POLICY

Under Corps authority, restoration opportunities that are associated with wetlands, riparian and other floodplain and aquatic systems are most appropriate for Corps involvement. The objective of Corps ecosystem restoration projects is to restore degraded ecosystem structure, function, and dynamic processes to a less degraded, more natural condition. Even partial restoration may provide significant and valuable improvements to degraded ecological resources (USACE 2000).

Restored ecosystems should mimic, as closely as possible, conditions that would occur in the area in the absence of human changes to the landscape and hydrology. Indicators of successful restoration would include the presence of a large variety of native plants and wildlife, the ability of the area to sustain larger numbers of key indicator species² or more biologically desirable species, and the ability of the restored area to continue to function and produce the desired habitat benefits with a minimum of continuing human intervention (USACE 2000).

Additional guidance for ecosystem restoration in the Civil Works Program assures that civil work investments in ecosystem restoration have the intended beneficial effects and would be conducted in the most cost effective manner (USACE 2000).

Corps guidance requires that the ecosystem related benefits of proposed alternatives be subjected

² An indicator species is an organism whose presence, absence or abundance reflects a specific environmental condition. Indicator species can signal a change in the biological condition of a particular ecosystem, and thus may be used as a proxy to diagnose the health of an ecosystem.

to detailed economic analysis, allowing an explicit comparison of the costs and benefits associated with the alternatives. Consequently, it is necessary that the environmental benefits of the alternatives be based on some quantifiable unit of value. Since restoration value is difficult to monetize, instead of calculating benefits in monetary terms, the Corps ecosystem restoration projects calculate the value and benefits of restored habitat using established habitat assessment methodologies. Comparing the alternatives in this manner facilitates the determination of the most cost-effective restoration alternative that meets restoration goals (USACE 2000).

5.2 HABITAT ASSESSMENTS

Evaluating habitat quality is the approach most often taken to compare ecosystem restoration alternatives because habitat is thought of as a surrogate for ecosystems; it is the setting where plants and animals live, interact, and reproduce. Habitat is frequently viewed in conjunction with species information to gain insight to various uses, structures, and functions existing within a landscape or site.

Few methods for habitat assessment exist; however, most are focused only on aquatic habitats, wetland habitats, or habitat for a single species. One such habitat assessment methodology used by the Corps is the U.S. Fish and Wildlife Service's (USFWS) single species model known as the Habitat Evaluation Procedure/Habitat Suitability Index Models (HEP/HSI) (1980). HEP evaluates single species, a species guild, or a species assemblage using models comprised of measureable habitat variables and associated mathematical aggregations to estimate habitat suitability/quality (NHI 2007). The preliminary output of the HEP model is a habitat suitability index (HSI), which ranges from 0 (poor habitat quality) to 1.0 (optimum habitat quality). Habitat value is finally calculated in terms of Habitat Units (HUs) by multiplying the HSI by site acreage.

HUs are then used to rate and compare the value of one ecosystem restoration alternative to another. While HUs are a simple and useful form for presenting habitat quality as a numerical value, HEP assumes a linear relationship between habitat suitability and species response. In other words, HEP assumes that as HSI increases the wildlife population should also increase. This implies that the model has the ability to predict population response without errors (NHI 2007).

Furthermore, the single species method assumes that an entire community is represented by that species, which may result in a narrow representation of habitat quality (NHI 2007). The single species method does not account for substantial benefits that are afforded by the ecosystem as a whole, which includes multiple species and multiple habitats. Furthermore, it does not account for all functions or habitat components potentially present at a site.

Throughout the U.S. there is a shift towards assessing restoration and other conservation activities at the ecosystem level (Perkins 2002). Determining habitat structure and functional integrity of an area for all species potentially using it is more supportive of an ecosystem management approach. A habitat assessment methodology that measures functionality, which is critical to the success of many restoration projects, should incorporate multiple components such as vegetation, structure, surrounding landscape, and habitat size and shape (Breaux et al. 2005, Store and Jokimaki 2003).

5.3 CHAP BACKGROUND

Recently, an ecosystem-based habitat evaluation framework known as HAB (or the Habitat Accounting and Appraisal methodology) was developed by the Northwest Habitat Institute (NHI). This approach involves a triad assessment of species, habitat, and functions (O’Neil et al. 2005), and includes an inventory of habitat components and their relationship to ecological functions performed by species. The Combined Habitat Assessment Protocols (CHAP) method, which incorporates the HAB methodology, generates HUs based on an assessment of multiple species, habitat features, and functions by habitat type.

In the HAB approach, fish and wildlife with the potential to occur at a given site are identified. Potential species are determined using range maps in conjunction with information on vegetation types and habitat types, structural conditions, and habitat elements, also known as Key Ecological Correlates (KECs). KECs represent habitat elements (physical and biological) that are known to most influence a species distribution, abundance, fitness, and viability. KECs include habitat elements such as down wood, snags, litter layer, shrub layer, flowers, burrows, boulders, or riffles and pools. For the Master list of CHAP KECs, see Appendix A.

Habitat is defined as “the place, including physical and biotic conditions, where a plant or animal usually occurs” (Johnson and O’Neil 2001). Habitat types are often characterized by a dominant plant form or physical characteristic. Structural conditions of the habitat are also considered.

Function refers to the principal way organisms influence the environment, also known as Key Ecological Functions (KEF) (NHI 2007). KEFs refer to the principal set of ecological roles performed by each species in its ecosystem (NHI 2007). More specifically, KEFs refer to the main ways organisms use, influence, and alter their biotic and abiotic environments. KEFs include functions that organisms perform in the environment, such as a grazer, sap feeder, carrion feeder, seed disperser, nest parasite, primary cavity excavator, or impounds water by creating dams. For the Master list of CHAP KEFs see Appendix B.

While other methods consider habitat components, the HAB approach considers over 350 different KECs and over 100 KEFs as seen in Appendices A and B. KECs and KEFs are key components in determining the wildlife habitat unit values.

The HAB approach can be combined with elements of HEP to address habitat value at evaluation sites, with HUs as the output. Such a combined approach is referred to as CHAP (Combined Habitat Assessment Protocol) (NHI 2007).

The CHAP evaluation described herein utilizes the ecosystem-based approach to quantitatively characterize the ecological value of wildlife habitat associated with the restoration alternatives proposed for the LA River ER Study. Habitats for the following groups of animals were evaluated as part of the CHAP analysis and would be benefited by implementation of the alternatives:

- Resident and Migratory Birds, including raptors
- Reptiles
- Amphibians

- Small mammals
- Fish

5.4 CORPS PLANNING PROCESS

In order to solve water resources and ecosystem restoration issues, the Corps Planning process identifies problems and opportunities, inventories and forecasts conditions, and formulates, evaluates, and compares alternative plans in order to select the best, most cost effective project alternative for implementation and construction.

In identifying problems and opportunities, project objectives and constraints are also developed that guide the formulation of alternatives. When inventorying and forecasting, the historic, existing, and future conditions are examined to establish a baseline for alternative comparison. Alternative formulation develops a suite of management measures³ that are combined together in various ways to create a set of project alternative plans. The alternative plans are evaluated by forecasting conditions “with project” implementation and comparing them to the forecasted “without project” condition. The plans are then compared to one another based on how they meet project objectives, and on cost effectiveness and cost-benefit analyses, policy compliance, and acceptability by the public and stakeholders. The best plan, based on these factors, becomes the recommended plan for implementation.

The habitat assessment serves to quantify restoration benefits that inform the cost effectiveness and cost-benefit analyses and that contribute to the comparison of alternative plans.

6.0 CHAP ANALYSIS

The HAB approach, which is largely spatially based, uses Geographic Information Systems (GIS) to delineate habitat polygons⁴ and map habitat types (cross-walked with associated vegetation types) within the Study area. These habitat type classifications are based on the California Wildlife Habitat Relationships (CWHR) habitat classification scheme, derived from the CDFG publication titled “A Guide to Wildlife Habitats of California” (Mayer and Laudenslayer 1988). For each habitat polygon, wildlife species associated with these CWHR habitat types are linked to key environmental correlates (KECs) (i.e. habitat elements) and key ecological functions (KEFs)(i.e. functions performed by species), which are derived from NHI’s Interactive Habitat and Biodiversity Information System (IBIS) database⁵ (Johnson and O’Neil, 2001).

The detailed steps of compiling KECs and KEFs are outlined in Section 6.1.1.

3 A management measure is a feature or activity that can be implemented at a specific geographic site to address one or more planning objectives. It may be a “structural” feature that requires construction or assembly on-site, or it may be a “non-structural” action that requires no construction (USACE 1996).

4 In GIS, a polygon is a map feature that bounds an area at a given scale, such as a county on a world map or a district on a city map. In habitat mapping, the polygon bounds a specific habitat type.

5 The datasets for KECs and KEFs have been developed through a multiple expert panel process. IBIS is an extensively peer reviewed system that contains current ecological information on more than 1,000 fish and wildlife species, organized in searchable databases.

The subsequent analysis of these habitats, species, and functions results in a quantitative value for existing and forecasted with and without project habitats in the Study area.

6.1 BASELINE: EXISTING CONDITIONS

6.1.1 Baseline: Existing Conditions Methods

A fine level scale approach was used to calculate habitat value for the LA River ER study. The baseline CHAP approach, incorporating the HAB methodology, involves: 1) preliminary mapping, 2) field inventory, 3) species list, 4) data compilation and analysis, 5) conversion to HUs, and 6) Annualizing HUs.

1. Preliminary Mapping

Using GIS and geo-referenced aerial imagery, the LA River ER study site was mapped by delineating potential habitat types or structural conditions within the site. Habitat types were identified using visual differences in land formations, vegetation, and structural condition, as detected and interpreted in the imagery. Preliminarily, the National Agriculture Imagery Program (NAIP) imagery was used, and later high-resolution imagery supplied by the Corps was used.

2. Field Inventory

The field inventory included an ocular survey that verified the polygon delineations. Habitat type, structural conditions, and key environmental correlates within each polygon were identified and recorded. Invasive plant species and the presence of stressors within each polygon were also recorded.

Stratified random verification transects were then employed to measure in detail the site's vegetation characteristics. These transects substantiate site variables including percent cover and species of trees, shrubs, herbaceous and invasive vegetation and serve as a double sampling technique to confirm the ocular field inventory.

3. Species List

The CWHR was used to produce a site-specific species list by considering ecological and geographical connections between species and the habitat types within the Study area. Factors used to generate the species list are potential species linked to each of the habitat types and potential species linked to the Study area based on species range maps and known existing conditions.

References from local experts including the Griffith Park Draft Wildlife Management Plan (Cooper and Mathewson 2008), The Biota of the Los Angeles River (Garrett 1993), and The State of the River – the Fish Study (FoLAR 2008), were also employed to develop an initial species list.

The species list was reviewed and refined by a habitat evaluation team (See Section 8.0) comprised of Corps and City of LA staff and local resource agency experts including the U.S. Fish and Wildlife Service (USFWS), California Department of Fish and Game (CDFG), Regional Water Quality Control Board (RWQCB), and a

local fish expert from the University of California Cooperative Extension, Los Angeles County. The team decided that seasonal migrants and infrequent visitors would be included on the species list, as creating an arbitrary limit for including a species as “occurring” would not account for all species that are known to use the project area. Additional review and input was requested from local experts including Dan Cooper (Cooper Ecological Monitoring, Inc.) and Drew Stokes (San Diego Natural Museum of History) to verify the presence or absence of certain species of interest. The resulting species list is included in Appendix C.

4. Data Compilation and Analysis

Data from the mapping and field inventory was used to generate two relationship matrices including 1) a potential species by function (KEFs) matrix and 2) a habitat (KECs) by function (KEFs) matrix (for definitions of KEC and KEF See Section 5.3; for further details on the matrices see Appendix D).

To create these matrices, the species list was sorted by its association with the CWHR habitat types and the list of taxa was linked to the associated habitat elements (KECs) and functions (KEFs).

The first matrix determines the mean functional redundancy index (MFRI), which is based on the number of species performing functions in a habitat type (KEFs). More specifically, it is the number of species that are associated with the habitat type and performing each function divided by the number of potential functions associated with the habitat type. The result of the first matrix is the number of potential functions characterized by species specific to that polygon.

The second matrix is based on the results of the field inventory of the Study area and the list of habitat elements (KECs) observed. The result of the second matrix is the number of functions characterized by habitat elements (KECs) specific to that polygon.

Per-acre values were then computed for each polygon by adding the species-function matrix (MFRI) value and the habitat-function matrix value (for further details on calculations see Appendix D). In sum, for each polygon MFRI + KEC matrix = Per Acre Value.

The per-acre value represents the intrinsic worth of an area to fish and wildlife, determined by accounting for species, habitats, and functions. Additional factors that may negatively impact this habitat value are accounted for as described in Section 6.1.2.

5. Conversion to HUs

To determine HUs for site conditions, in order to compare Study alternatives and inform alternative cost-benefit analyses, each polygon’s per-acre value was multiplied by its acreage. These values were then summed across all polygons to calculate the

total HUs for a particular condition or alternative scenario. In sum, for each polygon
 $\text{Per Acre Value} \times \text{Acres} = \text{HUs}$.

Unlike HEP, where the preliminary output (HSI) ranges from 0 to 1 (as described in Section 5.2), CHAP's per-acre values are not limited to this range. In this way, where the HUs in HEP are dependent on acreage ($\text{HSI} \times \text{acreage} = \text{HU}$; IE more acreage = more HUs), the HUs generated by CHAP are not dependent on acreage and reflect the intrinsic value of a particular habitat type based on species, functions, and habitat.

Results of the baseline CHAP analysis are provided in the form of GIS maps and Microsoft excel spreadsheets. GIS maps generated depict the habitat values (HUs) of each of the 172 polygons. Supporting maps illustrate: a) study area boundaries; b) polygon numbering; c) percentage of non-native plant species by polygon (See Section 6.1.2); d) wildlife habitat types by polygon (See Section 6.1.3); e) structural conditions by polygon (See Section 6.1.3); f) per-acre habitat value (See Section 6.1.3); and g) HUs (See Section 6.1.3).

Spreadsheets were developed that contain the calculations of the species-function and habitat-function matrices, along with calculations of Study area habitat values. Due to the large volume of data, maps, and spreadsheets, the complete set of files is available upon request from the Corps, Los Angeles District. Sample figures are provided in Figures 6.1.1-1, 6.1.2-1, and 6.1.3-1 to 6.1.3-8. Summary tables are included in Tables 6.1.3-1 and 6.1.3-3, and discussed in the following Sections 6.1.2 and 6.1.3.

6.1.2 Per-Acre Adjustment Value for Habitat Stressors

Since the LA River ER project area is located within a highly urbanized setting, there are several ecosystem drivers and stressors that affect the Study area and how it is currently managed. There are four noteworthy influences including: 1) invasive plant species, 2) potential use of the area for encampments by people who are homeless, 3) horseback riding in the river, and 4) excessive refuse/trash in the river.

Prior to conversion to HUs, the per-acre baseline value of each polygon was adjusted based on the presence of these stressors, in order to capture the value lost due to these factors within the Study area. The HAB method allows for these modifications when the habitat evaluation team deems them to be appropriate.

Invasive Plant Species

Each polygon was assigned an invasive plant value for each of three structural layers (grass/herbaceous, shrub, and tree) based on the presence and abundance of invasive species in that layer, as documented in the field inventory. Because invasive species generally negatively influence ecosystem function, the per-acre values were then discounted for the presence of invasives, to begin to arrive at a corrected per-acre value for each polygon. The value of discount applied based on presence of invasive species is described in Table 6.1.2-1. The deduction factor was multiplied by the per-acre value to reach the adjusted value. In sum, $\text{per-acre value} \times \text{deduction factor} = \text{adjusted per-acre value}$.

The percent abundance of invasive species by polygon can also be spatially displayed in a map to show their influence on the habitat value. Sample maps are included in Figure 6.1.2-1.

Table 6.1.2-1. Invasive plant species deduction factors⁶

Invasive species cover	X
0-10%	1.0
11-35%	0.9
36-65%	0.7
66-90%	0.5
>90%	0.3

Homeless, Horseback Riding, Excessive Refuse

During the habitat evaluation team meetings, the subject of homeless encampments, horseback riding, and excessive refuse/trash and their influence on wildlife habitat was raised. The team members were reluctant to assign an arbitrary value of influence to weight the polygons based on these stressors, so to address these concerns a literature review was conducted. Activities noted as potential effects to wildlife habitat from these stressors include trampling, camping, sewage, erosion, and covering. KECs that are influenced by these activities are found in Table 6.1.2-2. Since the CHAP identifies KECs as absent or present within each polygon, the stressor influenced KECs are adjusted by changing their status from present to absent. For example, the presence of homeless encampments would result in camping/trampling, which would damage vegetation. KECs such as flowers, forbs, shrubs, and saplings would, therefore, be identified as absent for those polygons. In applying this to the Study Area, these local stressors influenced the site's overall habitat value approximately 7%.

6.1.3 Baseline: Existing Conditions Results

Habitat Types and Vegetation Communities

The 172 polygons in the LA River ER Study area were determined by delineating the California Wildlife Habitat types that occur within the Study area. The mapping performed by NHI within the Study area in 2011 documented several habitat types, each of which are an aggregation of several vegetation communities. Habitat types as described by the CWHR System included Coastal Scrub, Eucalyptus, Open Water/Riverine, Pasture, Perennial Grassland, Valley Foothill Riparian, Tree Farm, and Urban (High Density, Golf Course, and Low Density). Structural conditions included: grass-forb, shrub, and tree layers along with constrained river channel and urban with various levels of impervious surfaces.

⁶ Deduction factors for invasive plant species were developed by NHI in a team environment during the Oregon Bridge Replacement Program, where agencies wanted to receive credit for controlling invasive species at a site. The team was comprised of representatives from: U.S. Army Corps of Engineers, Bureau of Land Management, NOAA Fisheries Service, Environmental Protection Agency, U.S. Forest Service, U.S. Fish and Wildlife Service, Federal Highway Administration, Oregon Department of Transportation, Oregon Department of Environmental Quality, Oregon Department of Fish and Wildlife, Oregon Department of State Lands, and the State Historic Preservation Office.

Refuse/Trash	4.1.11	metals in water	depending on type
Refuse/Trash	8.19.3	pollution in water	depending on type
Refuse/Trash	5.9	water clarity	covering/depending on type

Vegetation communities associated with each habitat type are described below, as applicable, as documented in both “A Manual of California Vegetation” (2nd Edition) (Sawyer and Keeler-Wolf 2009) and “Preliminary Descriptions of the Terrestrial Communities of California” (Holland 1986).

1. Coastal Scrub

Vegetation Communities

Holland 1986

- Riversidean Sage Scrub 32700

Sawyer and Keeler-Wolf 2009

- *Artemisia californica* Shrubland Alliance (California sagebrush scrub)

Dominant species include California sagebrush (*Artemisia californica*) and California buckwheat (*Eriogonum fasciculatum*). This community is typically found on xeric sites such as steep slopes or well drained soils. Co-dominant species include brittlebush (*Encelia farinosa*), deerweed (*Lotus scoparius*), chaparral mallow (*Malacothamnus fasciculatus*), and white and black sage (*Salvia apiana* and *S. mellifera*).

2. Eucalyptus

Vegetation Communities

Sawyer and Keeler-Wolf 2009

- *Eucalyptus (globules, camaldulensis)* Alliance (Eucalyptus groves) (semi-natural woodland stands)

Several species of eucalyptus including blue gum, red gum, and silver gum are established in dense, pure stands and are typically adjacent to urban areas and non-native grasses.

3. Open Water - Riverine

Vegetation Communities

Holland 1986

- Freshwater Marsh 52400

Sawyer and Keeler-Wolf 2009

- *Arundo donax* Semi-Natural Herbaceous Stands (Giant reed breaks)
- *Typha (angustifolia, domingensis, latifolia)* Herbaceous Alliance (Cattail marshes)
- *Schoenoplectus californicus* Herbaceous Alliance

Dominant species include cattails (*Typha* sp.), sedges, and rushes, as well as non-native invasive arundo (*Arundo donax*), in areas permanently saturated or flooded by freshwater.

Intermittent or continually running water distinguishes river and stream communities. Streams originate at an elevated source, such as a spring or lake, and flow velocity generally declines at progressively lower altitudes (Mayer and Laudenslayer 1988). These areas are considered to have a minimum of vegetation components, except along the edges, which may be mapped (in this case) as types such as freshwater marsh.

In the higher velocity stretches of natural streams, riffle/pool complexes are dominant and vegetation includes water moss and filamentous algae that are attached to rocks. In slower moving waters, with increasing temperatures, decreasing velocities and accumulating bottom sediment, emergent freshwater marsh vegetation, such as rushes, sedges, and cattails, establishes along river banks (Mayer and Laudenslayer 1988).

4. Pasture

Vegetation Communities

Holland 1986

- Non-native grassland 42200

Sawyer and Keeler-Wolf 2009

- *Conium maculatum* – *Foeniculum vulgare* Semi-Natural Herbaceous Stands (Poison hemlock or fennel patches)

Dominant species include non-natives such as fennel (*Foeniculum vulgare*), bromes (*Bromus* sp.), wild oat (*Avena* sp.), red-stem filaree (*Erodium cicutarium*), fescues (*Vulpia* sp.), and mustard (*Brassica* sp.). Scattered trees may also be present.

5. Perennial Grassland (Invasive)

Vegetation Communities

Holland 1986

- Non-native grassland 42200

Sawyer and Keeler-Wolf 2009

- *Conium maculatum* – *Foeniculum vulgare* Semi-Natural Herbaceous Stands (Poison hemlock or fennel patches)

Invasive Perennial Grassland is similar in composition to Pasture, where relic perennial grassland occurs in habitats now dominated by annual grasses and forbs (Mayer and Laudenslayer 1988).

6. Valley Foothill Riparian

Vegetation Communities

Holland 1986

- Southern Cottonwood-Willow Riparian Forest 61330
- Southern Willow Scrub 63320

Sawyer and Keeler-Wolf 2009

- *Salix gooddingii* Woodland Alliance (black willow thickets)
- *Salix laevigata* Woodland Alliance (red willow thickets)
- *Populus fremontii* Forest Alliance (Fremont cottonwood forest)

Dominant species include cottonwood (*Populus fremontii*), western sycamore (*Platanus racemosa*), and willows (*Salix* sp.). Forest understory may consist of shrubby willows and mule fat (*Baccharis salicifolia*) with herbaceous species including sedges, rushes, and mugwort (*Artemisia douglasiana*). Scrub habitat has less vertical structure, with shorter willows dominant.

7. Tree Farm

Ornamental or non-native hardwood species dominate this community, although other non-native conifers, shrubs, and grasses may be present. These communities are usually in developed areas, including urban and residential landscapes, parks, recreational areas, highways, and cemeteries, etc. and may include potted landscaping trees (USFS 2009).

8. Urban

This category includes landscapes dominated by urban structures, residential units, industrial areas, highways, parks, and other such structures (USFS 2009). Park areas may include alternately categorized vegetation such as non-native or ornamental. Urban areas are categorized as:

- High density
- Low density
- Golf course

The acreage of each habitat type by reach is shown in Table 6.1.3-1. To demonstrate the habitat mapping results, sample maps depicting habitat type and structural conditions are included in Figures 6.1.3-1 and 6.1.3-2.

Table 6.1.3-1. Acreage of Habitat Type by Reach

Habitat Findings

Vegetation transects were employed to verify the results of the habitat inventory that occurred at the LA River ER Study site. Results of these verification transects are included in the LA River CHAP Verification Transect Report (Ashley 2010) (Appendix E). Figure 6.1.3-3 shows the location of the verification transects. Table 6.1.3-2 outlines a list of plant species encountered either along or near the verification line transects.

Habitat Units

The habitat assessment shows ten habitat types currently existing within the Study area, totaling approximately 842 acres. The acreage of each of the habitat types and their proportion of the total study area are depicted in Table 6.1.3-3. The baseline existing condition assessment calculated that these acres have a total value of 6,119 HUs. Graphs depicting acreage by habitat type and per-acre habitat value by habitat type follow in Figures 6.1.3-4 and 6.1.3-5. Sample figures depicting per-acre value and HUs are included in Figures 6.1.3-6 and 6.1.3-7.

Mapping of habitat types for baseline existing conditions shows that approximately 67% of the Study area (564.85 acres) is urban (including low density and golf course), providing an average 4.64 HUs per acre. Existing riparian habitat accounts for only 7% of the Study area (62.42 acres), however it provides 16.84 HUs per acre. These riparian areas occupy 9 times fewer acres than the urban areas, yet provide almost four times more HUs per acre than the urban areas. The open water areas also provide substantial HUs per acre, totaling 22% of the Study area (182.21 acres) and providing 11.89 HUs per acre. Other habitat types account for less than 4% of the Study area.

These conditions show that riparian and riverine restoration has the potential to provide substantial restored habitat function and value in the highly urban setting of Los Angeles, and that maximizing acreage of these habitats would benefit ecosystem functioning and species diversity in the area.

6.2 BASELINE: FIFTY YEAR FUTURE WITHOUT PROJECT

The future without project analysis forecasts the conditions in the Study area 50 years into the future assuming that no project is implemented (i.e. No Action alternative). The 50-year future without project analysis assesses two future time periods, 25 years and 50 years.

To undertake this assessment, several projections were made to assess habitats over the 50-year time period. These projections are based on past and current trends in habitat condition in the area. Specifically, reasonable predictions include: 1) an increase in presence of invasive plant species throughout the LA River ER Study area, 2) a large flood event (i.e. 500-year event) is likely to occur, and 3) fires threatening the project area will be suppressed.

The habitat evaluation team discussed a reduction in the number of fish and wildlife taxa present within the project area over time. However, in this case, it was the consensus of the habitat evaluation team that the current highly urban landscape conditions would prevail over time. Despite intense development pressure along certain areas of the river corridor, large swaths of existing open space (especially at Griffith Park) were expected to be conserved, consistent with long-established land use policies. Furthermore, it was assumed that native species are already

severely depressed, to nearly the maximum extent, given the impacts from urbanization. Therefore, it is assumed that the fish and wildlife species currently identified in the Study area, even under continued pressure from such stressors as invasive species, homeless encampments, horseback riding, and other urban uses, would likely prevail in the future. Thus, there were no adjustments made to the species list over the 50-year period.

Similarly, only minor adjustments to structural conditions were expected to occur from a simulated flood event. Due to the heavily urbanized environment surrounding the river and the engineered structure of the channel, conversion of wildlife habitat type and use by additional wildlife species would be unlikely. The riparian vegetation in the channel through the Glendale Narrows area has the potential to wash out during high flows, but would quickly recover, and has persisted through recent storm events.

6.2.1 Baseline: Future Without Project Methods

To determine a change in habitat values over time from the existing conditions, projections are needed to estimate changes to the species, habitat, and/or function parameters in the future. Applying these changes over several time periods requires some forecasting and theorizing to estimate the amount of alteration that might be expected during each time period. To display the future without project conditions and visualize these changes in value over time, changes to the habitat are applied to the fine scale habitat mapping, while changes to the species and functions, if any, are applied to their respective data sets.

The 25- and 50-year future without project analyses were built upon the baseline existing conditions analysis that illustrates the California wildlife habitat types within the Study area by GIS polygon (Figure 6.1.3-1). By modifying the species-habitat-function input information, which is based on the future projections for the area, a comparative time series evaluation over the 50-year period was generated.

Adjusting Species, Habitat or Functions

The habitat evaluation team met to generate projections for the 50-year future without project conditions. The rationale used by the habitat evaluation team, including logic and decision points, is included as follows.

1. Potential non-viable wildlife populations – The habitat evaluation team discussed the possibility of reducing or modifying the species list, however the team concluded that the current taxa, which are adapted to the highly urban environment surrounding the River, would most likely persist. It was assumed at the time of discussion that despite development pressure on the River, large open space areas, such as Griffith Park, were expected to be conserved due to high demand by the residents and established land use policies.
2. Invasive species would expand in area and abundance – Invasive plant species occurrence for baseline existing conditions was originally collected for three structural levels (the grass/forb layer, the shrub layer, and the tree layer) in each polygon. A discount factor

was applied based on the percentage of invasive species cover present, as shown in Table 6.1.2-1.

To determine the influence of invasive species for the future without project conditions, the habitat evaluation team forecasted that the presence and abundance of the invasive species would increase over time without implementation of a restoration project. Although occasional non-native and trash removal efforts are conducted by the Corps (and others) in certain reaches of the river, these efforts are not frequent or consistent, and are dependent on limited and unpredictable funding. They are also not conducted watershed-wide, so areas cleared of non-natives one year may be subject to re-infestation in later years. Therefore, it was estimated that the percentage of invasive species for each polygon at the baseline condition would advance to the next highest percentage level for the first 25 years, and to the subsequent level beyond that for the last 25 years. For example, if the baseline existing condition of a polygon exhibits 36-65% invasive cover in the grass/forb layer, then the condition at Year 25 would be assessed at 66-90% invasive cover, and the condition at Year 50 would be assessed at >90% invasive cover.

3. Flooding – A simulated 500-year flood event would likely have little influence on how the current wildlife population interacts with the landscape. It is possible that the riparian vegetation in the River within the soft-bottomed portions of the channel could be partially or even completely washed out by a 500-year event; however, historic photos indicate that current structural conditions are likely to persist in the soft-bottomed sections of the project area if no action is taken for the next 50 years. Riparian vegetation rapidly re-establishes after flood events, and this would be expected in the LA River channel. The project area outside the channel is extremely urbanized and any semi-natural areas would likely return to invasive shrub and grass conditions post-flood.

While a 500-year storm event may wash larger amounts of urban trash and detritus into the river, in its current state the River already contains substantial levels of trash in the Study area. The impacts of trash in the River were, therefore, expected to persist in the event of major flooding without project implementation. Overall, it was not expected that the number of species present or how those species interact with the landscape (habitat function) would be altered by flooding in the absence of a restoration project. Figure 6.2.1-1 depicts the overflow area for a 500-year flood event.

4. Fire – Griffith Park may be threatened by wildfire, however extreme effort is placed on suppressing the spread of wildfire near the Study area due to the threat to human life and property (infrastructure). The 2007 Griffith Park fire burned 817 acres, and a similar fire in 1961 burned 814 acres. Neither fire impacted the habitat within the Study area. There may be a greater concern over time for a potential increase in wildfire due to increased drought conditions associated with climate change. Maturing vegetation types and senescence would increase fuel loading and the potential for wildfire to spread to the Study area.

Therefore, the likelihood for at least one occurrence of a wildfire within the 50-year period has been projected based on the County's past fire history (Figure 6.2.1-2).

Figure 6.2.1-1. 500-year Flood Event – Overflow Area

Figure 6.2.1-2. LA County Fire History

Fire History from the Los Angeles County Fire Department illustrating the fires that have occurred from 1870s to 2005 [as reported in LA Times 08-05-2007].

Depending on the severity of a fire in the Study area, burned trees that do not suffer mortality may re-sprout from remnant vegetation and weedy species would likely return as ground cover. Over time some riparian vegetation in the Study area may re-establish from upstream seed sources, however weedy species would be expected to colonize quickly in the absence of established native vegetation. Without maintenance of non-native weeds, these species would be expected to further degrade existing riparian areas over time.

Some wildlife may benefit immediately after a fire, such as insectivorous birds that feed from post-fire insect outbreaks and cavity nesting birds and perching birds that find shelter and snags in the standing dead and damaged trees. Species that prefer structural diversity are generally expected to be negatively affected by a large stand-replacing fire in the Study area. A severe fire may change the water chemistry, leading to mortality of fish and other aquatic organisms. Loss of vegetation and the associated increase in sedimentation would also affect water quality for these species.

The Santa Ana winds, which can fan a wildfire into a major fire storm, were not considered a contributor to fire as the winds do not blow uniformly across Southern California and some areas, including the Study area, are relatively sheltered from the winds (Figure 6.2.1-3).

5. Planned Development – Currently, several development projects are anticipated to occur near the Study area. At the Headworks site, LA County Department of Water and Power is actively installing water tanks at the west end of the site. The Headworks site currently consists of a pile of fill dirt and hole for the future water tanks; therefore, KECs were altered for the area under the future without project condition to account for grass and shrub components that would be planted if no other action is taken at the site.

The California High Speed Train project is currently developing alternative alignments near the Study area. While the final alignment has not been determined, the alignment alternatives that abut and cross the Study area (if chosen) would have an impact on the value of wildlife habitat in the Study area under the future-without project scenario.

In the absence of an ecosystem restoration project on the River, urbanization will continue near the Study area, particularly in Downtown LA. Other development, transportation and infrastructure projects occurring within or adjacent to the Study area would generally have a negative effect on habitat value.

6. Earthquakes – Earthquakes and tremors occur frequently in the Southern California area. Figure 6.2.1-4 depicts the seismic activity that occurred in and around the Los Angeles area from 1800 thru 2000. In the event of an earthquake, the primary impact would be to infrastructure along the corridor. It is expected that the design and engineering of the channel, including pipelines and tanks, would withstand predictive earthquakes for the area. If this infrastructure failed, flooding may occur, although surface water would eventually flow back in the Los Angeles River.

Magnitude greater or equal to 5.5 California earthquakes, 1800-2000 (modified from Toppozada and Branum, 2002).

7. Proximity to Other Natural Areas – The Study area is in close proximity to other natural areas, most notably Griffith Park, which is the eastern terminus of the Santa Monica Mountains (Figure 6.2.1-5). It was expected that these substantial nearby open space areas and habitat connections would persist in the future.

6.2.2 Baseline: Future Without Project Results

After adjusting the percent of cover of invasive species and adjusting the KECs of each polygon based on planned development, flood and fire events, and climate change, habitat values were generated for the 25 and 50-year time periods.

As expected, habitat value is projected to substantially decline within the Study area assuming no restoration activity is implemented over the next 50 years. Open water areas and urban areas mostly comprised of impervious surfaces (including the concrete channel banks) showed no change from the current habitat value. The remainder of the Study area is projected to decline steadily in habitat value, with an overall decline of 7% after 25 years and 14% after 50 years (Figure 6.2.2-1). In the absence of restoration in the Study area, the existing riparian areas that currently provide the most habitat value per acre will continue to degrade. Ecosystem functions in the Study area will also continue to diminish.

The future without project CHAP calculations are included in Microsoft excel spreadsheets and displayed in a GIS geodatabase. Due to the large volume of these spreadsheets and data, the complete set of files is available upon request from the Corps, Los Angeles District.

6.2.3 Annualizing HUs

Since the amount and value of habitat found within the Study area is likely to vary over time, to account for time dependent variation habitat units were forecasted over the 50 year period of analysis. These 50 annualized values were then averaged to produce an average annual habitat unit value.

Annualized habitat unit values were generated by forecasting the amount and value of habitat expected to exist within the study area at discrete points of time during the period of analysis (i.e. the number of habitat units expected to exist in the 1st, 25th and 50th year of the period of analysis). The habitat values expected to exist in years between the forecast points were created by interpolating (linearly) between these forecast values. The resulting 50 habitat unit values (one for each year in the period of analysis) were then averaged to produce a single average annual habitat unit value. This annualized habitat value was compared to annualized costs in the economic cost effectiveness and incremental cost analyses (CE/ICA)(See Appendix B of the Main Feasibility Report).

6.3 ALTERNATIVES ANALYSIS

Through the Corps' Plan Formulation process, 19 preliminary ecosystem restoration alternatives were developed based on input from local stakeholders and resource agency groups provided at workshops throughout the planning process.

Figure 6.2.1-5. Proximity to other Natural Areas

Regional Connectivity to Local Mountain Ranges and Nationally Significant Areas

Opportunities for Connections to Griffith Park

Figure 6.2.2-1. Without Project HUs

HUs were calculated for each restoration alternative by evaluating specific habitat creation, improvement, and management actions within the Study area, where preliminary design specifications and future with project assumptions were clearly, spatially defined. Informed predictions of habitat value for each of the 19 preliminary restoration alternatives were made by altering the inputs to the CHAP to match the anticipated outcomes of the different restoration alternatives. Habitat value results were then tabulated for each alternative by reach.

6.3.1 Alternatives Methods

To calculate habitat value for each alternative, the species by function matrix values are adjusted when the species list changes or there is a conversion of habitat type. The habitat by function values are adjusted when KECs (i.e. habitat elements) are added or removed. Restoration activities can increase the values of either or both matrices within the CHAP accounting system.

By converting dense, urban uses to functioning riparian, open water, and marsh habitats, which are all aquatic ecosystems, the number of potential species linked to those habitats greatly increases in that area. The number of species performing functions and the number of functions provided by the habitat type also increases for that area. These adjustments in species, habitat, and functions lead to increased species by function matrix value for a given polygon. Adding KECs, such as by planting vegetation and creating geomorphology, or enhancing structures for wildlife use and connectivity, increases the habitat by function matrix values for a given polygon.

To calculate initial and future with project habitat values, representing the benefit of each alternative's proposed restoration activities, each of the total 172 CHAP polygons must be analyzed in terms of habitat type, structural conditions, and KECs expected to be present after restoration. For the purposes of the Study, habitat values were forecasted at initial HUs, after 25 years with project, and after 50 years with project. This provides a direct comparison to the baseline future without project conditions, at 25 and 50 years into the future.

The baseline CHAP polygons were delineated based on differences in habitat type or structural condition. During the alternatives analysis, some of the polygons established during baseline had to be split because different restoration actions were proposed in multiple areas within a given baseline polygon. In these cases the original CHAP baseline polygon number was retained, and any additional polygons resulting from split were labeled with a letter (e.g. polygon LAR_007 was split to LAR_007, LAR_007A and LAR_007B). Maintaining this continuity allowed for simplified spatial tracking.

After the polygons were split where necessary, and the new polygon acreages were calculated, each restoration measure was evaluated as to the habitat type it would create, and the structural condition and KECs expected to be present. The Corps' alternative matrix, describing alternative measures for each alternative per reach (Appendix F), was used to identify the sub-measures that occurred in each river reach for each alternative. Application of these sub-measures in certain areas dictated where habitat conversions would occur within the Study area for each alternative. Evaluations were also based on the proposed preliminary design cross sections (Appendix G),

habitat assumptions made by the design team related to management measures⁷ (Table 6.3.1-1), discussions with the CHAP habitat evaluation team, as well as projections of what current features would persist in a given polygon. To further assist in evaluating which sub-measures were to be implemented in each polygon, the design team's alternative GIS mapping (Tetra Tech 2012) was used as a spatial reference (Figure 6.3.1-1 and 6.3.1-2).

The following descriptions document the adjustments made to CHAP inputs (i.e. habitat type, KECs, percent invasives) to reflect the forecasted changes that would occur in each polygon with implementation of sub-measures from the restoration alternatives. Trash removal and invasives removal for the life of the project was included as a measure in any reach where restoration activities are proposed. For the complete list of measures, sub-measures, and their detailed descriptions, refer to Section 4.4 of the Main Feasibility Report. The master list of KECs and their numerical codes are included in Appendix A.

These descriptions are generalized for each sub-measure, and do not include polygon specific KECs such as roads, fences, bridges, buildings, and other anthropogenic features that were evaluated additionally for a given polygon.

For example, in polygons where the following sub-measures are implemented,

- Restore riparian and marsh by day lighting streams
- Creation of attenuation basin with wetlands

the following KECs were altered:

- Convert habitat type to Freshwater Emergent Wetland
- Restore all invasive species levels to 0-10%
- Remove trash and pollution KECs if applicable: 8.19.1 Chemical, 8.19.2 Sewage, 8.19.3 Water, 8.9 Refuse
- Add KECs: 4.1.2 Water Depth, 4.6.3.2 Emergent Vegetation, 4.7.1 Wetlands, 4.7.2.2 Non-Forest, 4.7.3 Size <2 ha, 4.7.4 Marsh Characteristics, 4.9 Seasonal Flooding, 8.16 Culverts, 8.24 Water Diversion

In other words, in polygons where a particular alternative designates that streams currently in storm drains be day lighted and the outlets/confluences be naturalized with created wetlands, it is expected that freshwater marsh would be restored and that invasives management would be implemented. Therefore, those KECs (habitat elements) should be accounted for in that polygon for the future with project condition. Trash management would also be implemented, which would remove certain existing habitat elements including chemical, sewage, and water pollution, and refuse. The restoration of wetlands would add KECs associated with that habitat such as emergent vegetation, seasonal flooding, and water diversions.

⁷ For the complete list of measures, sub-measures, and their detailed descriptions, refer to Section 4.4 of the Main Feasibility Report.

Table 6.3.1-1: Habitat Design Assumptions Related to Management Measures

Sub-Measure	Assumption
Restore riparian and marsh by day lighting streams	Average 1 acre wetland per site (confluence).
Create geomorphology and plant for freshwater marsh in adjacent side channel/in main LA River Channel. Create geomorphology for open water adjacent to the channel/in main LA River Channel.	Assume same percentage of wetland/riparian/open water as in existing soft bottom reaches.
Rebuild geomorphology for historic wash	Riparian.
Creation of attenuation basin with wetlands	Wetland.
Divert tributary & river flow into side channels	25% riparian/75% wetland.
Restructure/vegetate LA River concrete channel walls	This is applied to most of the channel banks but it is assumed that the banks will not be fully covered by vegetation. Assume 50% herbaceous riparian/50% concrete.
Habitat corridors/Riparian planting on over banks of the main channel or tributaries	50% riparian/50% shrub.
Terrace concrete banks/Planting built into modified channel walls	50% riparian/50% concrete*
Establish/improve open water habitat on concrete bottom areas within the main channel of the LA River	This measure is only in Reach 3. Assume 25% wetland (toe of the banks). Remaining stays as existing conditions.
Lower channel banks	One polygon adjacent to Verdugo Wash. Assume riparian.
Widen channel banks	Riparian.
Major tributary channels/widen channel	One polygon at Verdugo Wash. Assume same wetland/riparian percentage as existing conditions.
Terraces with earthen banks	Riparian.
In Soft Bottom Reaches 2, 4, 5, 6: Assume that the existing configuration of habitat in the channel bottom not modified. Assume trash cleanup and invasives management will be conducted for the life of the project in reaches where measures are implemented. Assume only occasional non-native/trash removal without the project.	
*Habitat composed of 50% riparian and 50% concrete would provide half of the benefits attained by the fully restored riparian habitat. While it does not provide as much benefit as the comprehensive riparian restoration, this habitat is an important component for wildlife movement and connectivity within the project area for small animals (mammals, birds, reptiles) in more restricted reaches, providing opportunities for foraging and cover. While concrete surfaces are not natural or a restored habitat, they do provide value to certain species, even if minimal value, in such a highly urbanized environment. Shorebirds benefit in areas of perennial flow where algae accumulates on the surface of the concrete. This provides them roosting and foraging habitat. This also serves as a linear open space corridor that wildlife can traverse without contending with traffic or other human intrusion. While persistence of concrete is not a restoration measure, it will continue to be a usable element for wildlife that will exist within the study area. The main purpose of the habitat evaluation is to ensure that with-project values are significantly better than without project for the overall study area. Concrete is an existing condition, and while the value may be low it is not zero in this particular case. If concrete surfaces are assigned zero value then the overall value of the entire study area (for both existing and future conditions) would be undervalued. With the project, there will be less concrete and less non-native vegetation.	

For the complete list of measures, sub-measures, and their detailed descriptions, refer to Section 4.4 of the Main Feasibility Report.

Figure 6.3.1-1. Sample Alternative Mapping – Alternative 1 – Reach 3

Figure 6.3.1-2. Sample Alternative Mapping – Alternative 1 – Reach 6

Similarly, the other sub-measures (below) would add or remove KECs to applicable polygons under the alternative future with project condition, based on the activities expected to occur for a particular alternative. The adjustments for each sub-measure are outlined as follows:

Create geomorphology and plant for freshwater marsh in adjacent side channel/in main LA River Channel

Create geomorphology for open water adjacent to the channel/in main LA River Channel

- Convert habitat type to Freshwater Emergent Wetland
- Restore all invasive species levels to 0-10%
- Remove trash and pollution KECs if applicable: 8.19.1 Chemical, 8.19.2 Sewage, 8.19.3 Water, 8.9 Refuse
- Add KECs: 4.1.2 Water Depth, 4.7.1 Riverine Wetland Characteristics, 4.6.3.2 Emergent Vegetation, 4.7.2.2 Non-Forest, 4.7.4 Marsh, 4.9 Seasonal Flooding, 8.16 Culverts, 8.24 Water Diversion Structures

Rebuild geomorphology for historic wash

Habitat corridors/Riparian planting on over banks of the main channel or tributaries

Widen channel banks

Terraces with earthen banks

- Convert habitat type to Valley Foothill Riparian
- Restore all invasive species levels to 0-10%
- Remove trash and pollution KECs if applicable: 8.19.1 Chemical, 8.19.2 Sewage, 8.19.3 Water, 8.9 Refuse
- Add KECs: 1.1.14.3.1 Seedling, 1.1.14.3.2 Sapling/Pole, 1.1.5 Moss, 1.1.6 Flowers, 1.1.7 Lichens, 1.1.8 Forbs, 1.1.13 Herbaceous Layer, 1.2.6.1.1 Small Shrub, 1.2.6.1.2 Medium Shrub, 3.2.3 Soil Moisture, 3.2.4 Soil Organic Matter

Divert tributary and river flow into side channels

- Convert habitat type to Freshwater Emergent Wetland
- Restore all invasive species levels to 0-10%
- Remove trash and pollution KECs if applicable: 8.19.1 Chemical, 8.19.2 Sewage, 8.19.3 Water, 8.9 Refuse
- Add KECs: 1.1.14.3.1 Seedling, 1.1.14.3.2 Sapling/Pole, 1.1.5 Moss, 1.1.6 Flowers, 1.1.7 Lichens, 1.1.8 Forbs, 1.1.13 Herbaceous Layer, 1.2.6.1.1 Small Shrub, 1.2.6.1.2 Medium Shrub, 3.2.3 Soil Moisture, 3.2.4 Soil Organic Matter, 8.24 Water Diversion, 4.7.1 Riverine Wetlands, 8.29 Regulated Hydrologic Regime

Restructure/vegetate LA River concrete channel walls

Terrace concrete banks/Planting built into modified channel walls

- Convert habitat type to Valley Foothill Riparian
- Restore all invasive species levels to 0-10%

- Remove trash and pollution KECs if applicable: 8.19.1 Chemical, 8.19.2 Sewage, 8.19.3 Water, 8.9 Refuse
- Add KECs: 1.1.5 Moss, 1.1.6 Flowers, 1.1.7 Lichens, 1.1.8 Forbs, 1.1.13 Herbaceous Layer, 1.2.6.1.1 Small Shrub, 1.2.6.1.2 Medium Shrub, 3.2.3 Soil Moisture, 3.2.4 Soil Organic Matter
- Apply restoration benefits to half of area (other half to remain concrete/baseline)

Establish/improve open water habitat on concrete bottom areas within the main channel of the LA River

- Convert habitat type to Open Water
- Remove trash and pollution KECs if applicable: 8.19.1 Chemical, 8.19.2 Sewage, 8.19.3 Water, 8.9 Refuse
- Add KECs: 4.1.2 Water Depth, 4.1.6 Water Velocity, 4.2.3.1 Open Water, 4.2.12 Banks

By adjusting the CHAP inputs based on the proposed restoration sub-measures, adjusting the individually unique inputs to each polygon, and calculating the CHAP matrices, per-acre HU values were generated for each polygon in each restoration alternative. KECs representing maturation of forecasted habitats (i.e. additional tree and shrub size classes, formation of downed wood and snags) were added to each polygon to predict the anticipated increased benefits of the restoration alternative at 25 and 50 years into the future. The per-acre value was then multiplied by the polygon acreage to obtain the total HUs for each polygon in each alternative.

The future with project CHAP calculations of habitat value are included in Microsoft excel spreadsheets and displayed in a GIS geodatabase. The design team's alternative mapping is also included in GIS. Due to the large volume of these spreadsheets and GIS data, the complete set of files is available upon request from the Corps, Los Angeles District. Sample figures depicting the alternative mapping and with project HUs are included in Figures 6.3.1-1 to 6.3.1-3. Summary tables are included in Table 6.3.2-1 and Appendix H, as discussed in the following Section 6.3.2.

6.3.2 Alternatives Results

By comparing the total with-project habitat value for each alternative to the baseline and without-project value, it is possible to isolate the benefits of the ecosystem restoration alternatives to fish and wildlife habitat. Table 6.3.2-1 outlines the gross and net benefits in HUs for the base year⁸, 25 years with project, and 50 years with project for each of the 19 preliminary alternatives. Gross benefits are the total benefits afforded by the alternative. Net benefits are the difference in benefits between the with- and without-project value; in other words the with project value minus the without project value. Here, the net benefits describe the increase in benefits afforded by the alternative over the without-project condition. Results are also presented in terms of Gross and Net Benefits by reach for each alternative in tables in Appendix H. Figure 6.3.2-1 depicts the gross benefits for each of the 19 alternatives at the base year, 25 years with project, and 50 years with project. Note that the names associated with each

⁸ Base year: the year when the proposed project is expected to be operational (USACE 2000)

*Gross Benefits = Total Benefits afforded by an alternative; Net Benefits = With Project Value – Without Project Value

** acreage values represent acres experiencing a change in habitat value, and are not necessarily consistent with total project acreage

*** total Habitat Units (HUs) for entire 842 acre Study area

Figure 6.3.2-1. Gross Benefits (HUs) for With Project Alternatives at Base Year, 25 Years With Project, and 50 Years With Project and the Baseline Condition

of the 19 alternatives in Table 6.3.2-1 were used by the project team to more simply distinguish between alternatives. Generally, for each alternative, there is an increase in habitat value over the without project conditions.

Alternatives 5 and 17 show a decrease in gross benefit from the 25 years future with project to 50 years future with project condition. Alternative 19 shows a decrease in gross benefits from the base year to 25 years future with project to 50 years future with project. This decrease in gross benefits over time is due to the degradation of other reaches in the Study area where no restoration activity would occur. For example, in Alternative 19, restoration activity would only occur in Reach 6. The remaining 7 of the 8 reaches in the project area would have no restoration activity implemented; therefore, over time the degradation of those remaining 7 reaches would depress the HUs for the entire Study area. While gross benefits decrease over time from the base year in those cases, net benefits remain positive for all alternatives. This means that all 19 alternatives have increased benefits over the without project condition.

Figure 6.3.2-2 further depicts the net benefits as HUs per reach per alternative at the base year, 25 years with project, and 50 years with project.

As expected, the Comprehensive Alternative 1, which includes all measures implemented in all reaches, provides the greatest increase in habitat value from without project conditions (i.e. net benefit), with a 111% increase in HUs at the base year over without project conditions and a 169% increase in HUs at year 50 over without project conditions. However, even the most minimal alternative 19, which includes measures in only one reach (Reach 6/Taylor Yard), still provides an 18% increase in HUs at the base year over the without project conditions and a 27% increase in HUs after 50 years over the without project conditions. The range of increase in net benefits among all 19 alternatives can be seen in Table 6.3.2-2.

6.3.3 Economic Analysis

The results of the CHAP analysis were annualized, as described in Section 6.2.3, to inform the Corps' economic analyses, which includes a Cost Effectiveness Analysis and an Incremental Cost Analysis (CE/ICA). These analyses are used to determine which alternative plans are the most cost effective, or produce a given amount of habitat value at the lowest possible cost, and which alternative plans are the best buys, or produce the most additional habitat value for the lowest additional cost.

In performing the CE/ICA analysis, the alternatives are broken down by reach, and alternative reaches are recombined to produce the most cost effective, best buy plans. In other words, different measures are implemented in each of the 8 reaches for each of the 19 alternative plans, resulting in a total of 8 x 19 (152) alternative reaches. These 152 alternative reaches are recombined, based on the CHAP benefits (HUs) and the restoration costs, into new cost effective/best buy alternative plans, such that (for example) the measures from Reach 1 in Alternative 11 are combined with the measures from Reach 2 in Alternative 16, and the measures from Reach 3 in Alternative 1, and so on.

The original 19 alternatives are not cost effective in themselves in that the best (i.e. most cost effective) ideas for each reach could not be expected to be produced in a single alternative plan

*Net Benefits = With Project Value – Without Project Value

** acreage values represent acres experiencing a change in habitat value, and are not necessarily consistent with total project acreage

*** % increase in HUs over the without project condition

during formulation. The determination of cost effectiveness is only made with detailed economic analysis. With the recombinations, therefore, the most cost effective ideas from each of the original 19 alternatives are combined into various new cost effective alternative plans. The final array of 4 of these new plans were chosen to be carried forward for further analysis in the Feasibility Study. The final array of 4 alternatives is described in detail in Section 4.14 of the Main Feasibility Report.

For additional detail on the CE/ICA analysis and the recombined cost effective alternative plans, see the Economic Appendix B in the Main Feasibility Report. For additional detail on the choice of alternative plans for the Final Array, see Section 4. of the Main Feasibility Report.

7.0 OTHER BENEFITS NOT CAPTURED IN CHAP

7.1 CONNECTIVITY

The CHAP analysis accounts for benefits provided by restored ecosystem functions, habitats, and species. There are, however, other types of benefits afforded by the restoration alternatives, including restoration of natural hydrology, that influences and supports restoration of biological systems. Restoration of movement corridors for wildlife is another benefit of restoration. Both hydrologic and wildlife connectivity has been lost since urbanization of the Study area and the channelization of the LA River in the early 20th century.

These benefits were considered in addition to the CHAP benefits to evaluate and compare the final array of alternatives, as described in Section 6.6 of the Main Feasibility Report.

7.1.1 Hydrologic and Hydraulic Connectivity - Reconnection of River to Floodplain

Hydrologic connections may be made naturally, by widening the river channel, removing artificial barriers, and allowing the river to naturally meander and reshape the adjacent floodplain area. Natural connections also support natural ecological processes such as exchange of sediment, nutrients, and energy between the river and floodplain. Connections may also be made artificially to support habitat, using river water to feed overbank sites via pipes, culverts, or pumps. Artificial connections are valuable to establish habitat, but are less capable of supporting other ecosystem processes and exchanges.

Maintaining ecological and evolutionary processes includes natural disturbance regimes, hydrologic processes, nutrient recycling and biotic interactions (EPA 1999). This benefit can only be achieved with reconnection of the river to its floodplain. This will protect the integrity of the ecosystem and increase sustainability. Biogeochemical interactions between the river and terrestrial sources are not as vital to riparian systems as overbank flow from floodplain connections (Hein 2003).

Floodplain connectivity also benefits restoration of fish habitat. Floodplain habitats provide critical spawning and rearing habitats for many large-river fishes. The standard that floodplains are essential habitats is often a key reason for restoring altered rivers to natural flow regimes (Burgess 2012).

Removal of concrete and widening restores ecosystem processes such as natural disturbance,

hydrology, nutrient cycling, biotic interactions, population dynamics, and evolution, which determine the species composition, habitat structure, and ecological health of an ecosystem (EPA 1999). Channel widening would allow the river to connect to the overbank, which restores a dynamic floodplain and supports diverse riparian and in stream habitat for plants and wildlife.

7.1.2 Wildlife Connectivity

River channels in arid and semi-arid regions provide important wildlife movement corridors because they support continuous chains of vegetation that wildlife can use for cover and food (which may not be supported in drier upland habitats). These river corridors naturally guide wildlife movement, both daily and generationally, which is essential to species survival (Levick et al. 2008).

The remaining fragments of habitat in the urban landscape (or habitat “nodes”) benefit the integrity of the larger ecosystem by supporting metapopulations (assemblages of local populations connected by migration) (Hanski & Gilpin 1991). By increasing patches and reducing the distances between them, colonization among populations improves (Hanski & Thomas 1994). Metapopulations depend on seed dispersal and wildlife movements to persist, and such dispersal is in turn dependent on the connectivity of the landscape (Schippers et al 1996).

Nodes may be larger or smaller. Large habitat nodes support colonization of wildlife in the smaller nodes, while smaller nodes act as peripheral refuge habitat (Rudd et al. 2002). Large nodes tend to have high biodiversity and provide important breeding and seeding habitat for interior species, as well as edge species and transients. Smaller nodes are partly or entirely dependent on individuals immigrating from the larger nodes as they have a higher rate of extinction and therefore need to be repopulated constantly (Hansson 1991; van Apeldoorn et al. 1992). Smaller nodes (those under 250 acres) may not be able to support large numbers of species on their own but are able to provide important peripheral habitat to species in the larger nodes (Hansson 1991).

Generally, nodes have a greater overall interaction when they are larger and closer together (Linehan et al 1995). Well connected systems prevent inbreeding depression and disease, and have a lower extinction rate as populations can more easily colonize if they are highly connected (Noss 1983; Schippers et al 1996). Without connections between habitat areas, isolation and loss of genetic diversity is imminent (Hobbs & Saunders 1990).

In order to benefit the biological integrity of a landscape, corridors should be restored to allow for dispersal between habitat areas. More corridors equal more routes to suitable habitat, creating more opportunities for dispersal. A complex network of nodes and corridors is therefore critical to restoration in an urban environment, as suitable habitat often remains unused if isolated (Hanski & Thomas 1994).

Restoring connectivity for wildlife and movement between patches of habitat provides several benefits including reconnecting genetically isolated populations of species and preventing inbreeding depression, providing necessary interactions between predators and prey to control population size and providing a healthy ecosystem balance, and connecting individual wildlife to

required resources that may not be present within one isolated area.

7.2 ECONOMIC

Other benefits include installation of recreational features and regional economic development (RED) benefits. RED benefits may include increases in employment and regional income/gross regional product (GRP) resulting from the project. Benefits may also include other social effects that have value that were not explicitly valued in monetary terms, such as increases in "community cohesion" or carbon offsets from the installation of carbon sequestering vegetation.

These benefits are accounted for in the narrative of the Main Feasibility Report in Section 6.6.

8.0 CHAP HABITAT EVALUATION TEAM

8.1 PARTICIPANTS

The CHAP Habitat Evaluation Team consisted of the following representatives from the USACE environmental and plan formulation branches, City of Los Angeles Bureau of Engineering (BOE), Northwest Habitat Institute (NHI), U.S. Fish and Wildlife Service (USFWS), Regional Water Quality Control Board (RWQCB), California Department of Fish and Game (CDFG), and U.C. Cooperative Extension. The CHAP analysis team members based their evaluation on expertise in local ecology, plants and wildlife, study objectives, and field visits to the project site. The team members are listed below:

- Erin Jones, Biologist, U.S. Army Corps of Engineers, Planning Division
- Kathleen Bergmann, Study Manager, U.S. Army Corps of Engineers, Planning Division
- Larry Hsu, City of Los Angeles, formerly Bureau of Engineering
- Tom O'Neil, Northwest Habitat Institute
- Andy Hackethorn, Northwest Habitat Institute
- Scott Estergard, Tetra Tech
- Peter Beck, U.S. Fish and Wildlife Service
- Shirley Birosik, Regional Water Quality Control Board, Los Angeles Region
- Scott Harris, California Department of Fish and Game
- Sabrina Drill, U.C. Cooperative Extension, Los Angeles County

8.2 MEETINGS

Habitat evaluation team meetings were held at the Corps' Los Angeles District Office to discuss baseline existing conditions, baseline future without project conditions, and future with project conditions. Meetings were held on January 7, 2010; April 21, 2010; and November 3, 2011.

9.0 CONCLUSION

The CHAP analysis is a habitat assessment tool that evaluates habitats, functions, and species to quantify habitat value. For the LA River ER Feasibility Study, CHAP was used to quantify the value, or benefits, of various restoration alternatives in terms of Habitat Units (HUs) in order to compare alternative plans. Habitat value was calculated for baseline conditions including the

future without project conditions at 25 and 50 years into the future. Habitat value was also calculated for the 19 restoration alternatives developed during the plan formulation process.

The benefits of each restoration alternative were used with project costs to inform the economic cost effectiveness and incremental cost analysis. This analysis recombined the 8 reaches among the 19 alternatives, resulting in an array of new cost effective alternative plans. The final array of 4 of these new plans was chosen to be carried forward for further analysis in the Feasibility Study.

Additional benefits not captured in CHAP were used to evaluate and compare the final array of alternatives. These benefits include hydrologic connectivity to support biotic and abiotic functions, and nodal connectivity to support wildlife movement and dispersal. An assessment of these benefits is applied outside of the CHAP analysis as part of the environmental impact analysis.

CHAP Appendix
Appendix A
Master List Key Ecological Correlates (KECs)

KEC #	KEC Name	KEC Definition
1.1.1	down wood	Includes downed logs, branches, and rootwads, in a forested context.
1.1.1.1	decay class	System by which down wood is classified based on its deterioration.
1.1.1.1.1	hard [class 1,2]	Little wood decay evident; bark and branches present; log resting on branches, not fully in contact with ground; includes classes 1 and 2 as described in Thomas (1979).
1.1.1.1.2	moderate [class 3]	Moderate decay present; some branches and bark missing or loose; most of log in contact with ground; includes class 3 as described in Thomas (1979).
1.1.1.1.3	soft [class 4, 5]	Well decayed logs; bark and branches missing; fully in contact with ground; includes classes 4 and 5 as described in Thomas (1979).
1.1.1.2	down wood in riparian areas	Includes down wood in the terrestrial portion of riparian zones in forest habitats. Does not refer to in-stream woody debris.
1.1.1.3	down wood in upland areas	Includes downed wood in upland areas of forest habitats.
1.1.1.4	size of down wood	Count all down wood $\geq$ 6 feet long.
1.1.1.4.1	small	$\leq$ 5 inches large end diameter
1.1.1.4.2	medium	$>$ 5 to $<$ 20 inches large end diameter
1.1.1.4.3	large	$\geq$ 20 inches large end diameter
1.1.2	litter	The upper layer of loose, organic (primarily vegetative) debris on the forest floor. Decomposition may have begun, but components still recognizable.
1.1.3	duff	The matted layer of organic debris beneath the litter layer. Decomposition more advanced than in litter layer; intergrades with uppermost humus layer of soil.
1.1.4	shrub layer	Refers to the shrub strata within forest stands.
1.1.4.1	shrub size	Refers to shrub height. Select all categories present within the map unit.
1.1.4.1.1	small shrubs	$<$ 20 inches
1.1.4.1.2	medium shrubs	20 inches - 6.5 feet
1.1.4.1.3	large shrubs	6.6 feet - 16.5 feet
1.1.4.2	percent shrub canopy cover	Percent of ground covered by vertical projection of shrub crown diameter.
1.1.4.3	shrub canopy layers	Within a shrub community, differences in shrub height and growth-form produce multi-layered shrub canopies in the forest understory.
1.1.5	moss	Large group of nonvascular green plants without flowers but with small leafy stems growing in clumps.
1.1.6	flowers	A modified plant branch for the production of seeds and bearing leaves specialized into floral organs.
1.1.7	lichens	Any of a various complex of lower plants made up of an alga and a fungus growing as a unit on a solid surface.
1.1.8	forbs	Broad-leaved herbaceous plants. Does not include: grasses, sedges or rushes.
1.1.9	cactus	Any of a large group of drought-resistant plants with fleshy, usually jointed stems and leaves replaced by scales or prickles.
1.1.10	fungi	Mushrooms, molds, yeasts, rusts, etc.
1.1.11	roots, tubers, underground plant parts	Any underground part of a plant that functions in nutrient absorption, aeration, storage, reproduction and/or anchorage.
1.1.12	ferns	Any of a group of flowerless, seedless vascular green plants.
1.1.13	herbaceous layer	Understory non-woody vegetation layer beneath shrub layer (forest context). May include forbs, grasses, and ferns.
1.1.14	trees	Includes both coniferous and hardwood species.
1.1.14.1	snags	Standing dead trees.
1.1.14.1.1	decay class	System by which snags are classified based on their deterioration.
1.1.14.1.1.1	hard [class 1, 2]	Little wood decay evident; bark, branches, top, present; recently dead; includes class 1 as described in Brown
1.1.14.1.1.2	moderate [class 3]	Moderately decayed wood; some branches and bark missing and/or loose; top broken; includes classes 2 and 3 as described in Brown (1985).
1.1.14.1.1.3	soft [class 4, 5]	Well-decayed wood; bark and branches generally absent; top broken; includes classes 4 and 5 as described in Brown (1985).
1.1.14.2	snag size (dbh)	Measured in diameter at breast height (dbh), the standard measurement for standing trees taken at 4.5 feet above the ground.
1.1.14.2.1	seedling	$<$ 1 inch
1.1.14.2.2	sapling/pole	1 - 9 inches
1.1.14.2.3	small tree	10 - 14 inches
1.1.14.2.4	medium tree	15 - 19 inches
1.1.14.2.5	large tree	20 - 29 inches
1.1.14.2.6	giant tree	$\geq$ 30 inches
1.1.14.3	tree size (dbh)	Measured in diameter at breast height (dbh), the standard measurement for standing trees taken at 4.5 feet above the ground.
1.1.14.3.1	seedling	$<$ 1 inch
1.1.14.3.2	sapling/pole	1 - 9 inches
1.1.14.3.3	small tree	10 - 14 inches
1.1.14.3.4	medium tree	15 - 19 inches
1.1.14.3.5	large tree	20 - 29 inches
1.1.14.3.6	giant tree	$\geq$ 30 inches
1.1.14.4	mistletoe brooms/witches brooms	Dense masses of deformed branches caused by any type of broom-forming parasite (fungal or plant).
1.1.14.5	dead parts of live tree	Portions of live trees with rot; can include broken tops; branches with decay; tree base with rot.
1.1.14.6	hollow living trees (chimney trees)	Tree bole with large hollow chambers.
1.1.14.7	tree cavities	Smaller chamber in a tree; can be in bole, limbs, or forks of live or dead trees. May be excavated or result from decay or damage.
1.1.14.8	bark	Includes crevices/fissures, loose or exfoliating bark.
1.1.14.9	live remnant/legacy trees	A live mature or old-growth tree remaining from the previous stand. Context is remnant trees in recently harvested or burned stands up through young forested stands. See dead parts of live trees, hollow living trees, tree cavities, an bark to see which species benefit from remnant trees with these attributes.
1.1.14.10	large live tree branches	Large branches often growing horizontally out from the tree bole.
1.1.14.11	tree canopy layer	Refers to the strata occupied by tree crowns.
1.1.14.11.1	sub-canopy	The space below the predominant tree crowns.
1.1.14.11.2	above canopy	The space above the predominant tree crowns.
1.1.14.11.3	tree bole	The tree trunk.
1.1.14.11.4	canopy	The more or less continuous cover of branches and foliage formed collectively by the crowns of adjacent trees and other woody growth.
1.1.15	fruits/seeds/nuts	Plant reproductive bodies that are used by animals.
1.1.16	edges	The place where plant communities meet or where successive stages or vegetative conditions within plant communities come together; an edge between 2 different habitat types; only record this one time (i.e. don't record for both of the habitat types).

1.2	Shrubland/Grassland Vegetative Elements or Substrates	Biotic components found within a shrubland or grassland context. Positive influences only.
1.2.1	herbaceous layer	Zone of understory non-woody vegetation beneath shrub layer (non-forest context). May include forbs, grasses.
1.2.2	fruits/seeds/nuts	Plant reproductive bodies that are used by animals.
1.2.3	moss	Large group of nonvascular green plants without flowers but with small leafy stems growing in clumps; record moss found in trees, shrubs, etc.; do NOT record moss found on soil surface (this is recorded in KEC 1.2.11).
1.2.4	cactus	Any of a large group of drought-resistant plants with fleshy, usually jointed stems and leaves replaced by scales or prickles.
1.2.5	flowers	A modified plant branch for the production of seeds and bearing leaves specialized into floral organs.
1.2.6	shrubs	Plant with persistent woody stems and less than 16 feet tall; usually produces several basal shoots as opposed to a single bole.
1.2.6.1	shrub size	Refers to height.
1.2.6.1.1	small	< 20 inches
1.2.6.1.2	medium	20 inches - 6.5 feet
1.2.6.1.3	large	6.6 feet - 16.5 feet
1.2.6.2	percent shrub canopy cover	Percent of ground covered by vertical projection of shrub crown diameter.
1.2.6.2.1	<5%	
1.2.6.2.2	21-35%	
1.2.6.2.3	36-50%	
1.2.6.2.4	>50%	
1.2.6.3	shrub canopy layer	Within a shrub community, differences in shrub height and growth form produce multi-layered shrub canopies.
1.2.6.3.1	sub-canopy	The space below the predominant shrub crowns.
1.2.6.3.2	above canopy	The space above the predominant shrub crowns.
1.2.7	fungi	Mushrooms, molds, yeasts, rusts, etc.
1.2.8	forbs	Broad-leaved herbaceous plants. Does not include: grasses, sedges or rushes.
1.2.9	bulbs/tubers	Any underground part of a plant that functions in nutrient absorption, aeration, storage, reproduction and/or
1.2.10	grasses	Members of the Poaceae (Graminae) family.
1.2.11	cryptogamic crusts	Non-vascular plants that grow on the soil surface. Primarily lichens, mosses and algae. Often found in arid or semi-arid regions. May form soil surface "pinnacles".
1.2.12	trees (located in a shrubland/grassland context)	Small groups of trees or isolated individuals.
1.2.12.1	snags	Standing dead trees.
1.2.12.1.1	decay class	System by which snags are classified based on their deterioration.
1.2.12.1.1.1	hard	Little wood decay evident; bark, branches, top, present; recently dead; includes class 1 as described in Brown
1.2.12.1.1.2	moderate	Moderately decayed wood; some branches and bark missing and/or loose; top broken; includes classes 2 and 3 as describe din Brown (1985).
1.2.12.1.1.3	soft	Well-decayed wood; bark and branches generally absent; top broken; includes classes 4 and 5 as described in Brown (1985).
1.2.12.2	snag size (dbh)	Measured in diameter at breast height (dbh), the standard measurement for standing trees taken at 4.5 feet above the ground.
1.2.12.2.1	seedling	< 1 inch
1.2.12.2.2	sapling/pole	1 - 9 inches
1.2.12.2.3	small tree	10 - 14 inches
1.2.12.2.4	medium tree	15 - 19 inches
1.2.12.2.5	large tree	20 - 29 inches
1.2.12.2.6	giant tree	>= 30 inches
1.2.12.3	tree size (dbh)	Measured in diameter at breast height (dbh), the standard measurement for standing trees taken at 4.5 feet above the ground.
1.2.12.3.1	seedling	< 1 inch
1.2.12.3.2	sapling/pole	1 - 9 inches
1.2.12.3.3	small tree	10 - 14 inches
1.2.12.3.4	medium tree	15 - 19 inches
1.2.12.3.5	large tree	20 - 29 inches
1.2.12.3.6	giant tree	>= 30 inches
1.2.13	edges	The place where plant communities meet or where successive stages or vegetative conditions within plant communities come together.
2.0	Influences by Other Organisms	Selected interspecies relationships within the biotic community. Both positive and negative influences.
2.1	exotic species	When checked, these KECs refer to the relationship between an exotic species and the species queried by the user. This relationship may be positive or negative, and the user should refer to the comments section for further information. Exotic species are defined as any non-native plant or animal, including cats, dogs, and cattle.
2.1.1	exotic plants	This field refers to the relationship between an exotic plant species and the animal species queried by the user. This relationship may be positive or negative, and the user should refer to the comments section for further information. If no specific species of interest is known, only check if exotic plant presence is obvious and list the
2.1.2	exotic animals	This field refers to the relationship between an exotic animal species and the animal species queried by the user. This relationship may be positive or negative, and the user should refer to the comments section for further information. If applicable, the user will also find clarification of how the species queried is affected by the exotic species in HE subcategories 2.1.2.1 - 2.1.2.3. If no specific species of interest is known, only check if exotic animal presence is obvious and list the species.
2.1.2.1	predation	The species queried is preyed upon by or preys upon an exotic species. If no specific species of interest is known, only check if exotic animal predation is obvious and list the species.
2.1.2.2	direct displacement	The species queried is physically displaced by an exotic species, either by competition or actual disturbance. If no specific species of interest is known, only check if direct displacement by an exotic animal is obvious and list the species.
2.1.2.3	habitat structure change	The species queried is affected by habitat structural changes caused by an exotic species, for example, cattle grazing. If no specific species of interest is known, only check if habitat structure changes by exotic animals are obvious and list the species.
2.1.2.4	other	Any other effects of an exotic species on a native species (not used by panelists).
2.2	insect population irruptions	The queried species directly benefits from insect population eruptions (i.e., benefits from the insects themselves, not the resulting tree mortality or loss of foliage).
2.2.1	mountain pine beetle	The queried species directly benefits from Mountain Pine Beetle eruptions.
2.2.2	spruce budworm	The queried species directly benefits from Spruce Budworm eruptions.
2.2.3	douglas-fir tussock moth	The queried species directly benefits from Douglas-fir Tussock Moth eruptions (not used by panelists).
2.2.4	other	

2.3	beaver/muskrat activity (dams, lodges, ponds)	The results of beaver activity including dams, lodges, and ponds, that are beneficial to other species.
2.4	burrows (aquatic or terrestrial)	Aquatic or terrestrial cavities produced by burrowing animals that are beneficial to other species.
2.5	pathogens	Fish pathogens
3.0	Non-Vegetative, Abiotic Habitat Elements	Non-living components found within any ecosystem. Primarily positive influences with a few exceptions as indicated.
3.1	rocks	Solid mineral deposits.
3.1.1	gravel	Particle size from 0.1-3.0-inches diameter; gravel bars associated with streams and rivers are a separate category.
3.1.2	talus	Accumulations of rocks at the base of cliffs or steep slopes; rock/boulder sizes varied and determine what species can inhabit the spaces between them.
3.1.3	talus-like habitats	Refers to areas that contain many rocks and boulders but are not associated with cliffs or steep slopes.
3.2	soils	Various soil characteristics.
3.2.1	soil depth	Enter the distance from the top layer of the soil to the bedrock or hardpan below, measured in feet. Note, only complete this field if you are actually sampling soil depth.
3.2.2	soil temperature	Enter the measure of soil temperature or range of temperatures that are key to the queried species, measured in degrees F. Note, only complete this field if you are actually sampling soil temperature.
3.2.3	soil moisture	Enter the amount of water contained within the soil as a percentage. Note, only complete this field if you are actually sampling soil moisture.
3.2.4	soil organic matter	The accumulation of decomposing plant and animal materials found within the soil.
3.2.5	soil texture	Refers to size distribution and amount of mineral particles (sand, silt, and clay) in the soil; examples are sandy clay, sandy loam, silty clay etc.
3.2.6	no correlation	
3.3	rock substrates	Various rock formations.
3.3.1	avalanche chute	An area where periodic snow or rockslides prevent the establishment of forest conditions; typically shrub and herb dominated (Sitka alder and/or vine maple).
3.3.2	cliffs	A high, steep formation, usually of rock. Coastal cliffs are a separate category under Marine Habitat Elements.
3.3.3	caves	An underground chamber open to the surface with varied opening diameters and depths; includes cliff-face caves, intact lava tubes, coastal caves, and mine shafts.
3.3.4	rocky outcrops and ridges	Areas of exposed rock.
3.3.5	rock crevices	Refers to the joint spaces in cliffs, and fissures and openings between slab rock; crevices among rocks and boulders in talus fields are a separate category (talus).
3.3.6	barren ground	Bare exposed soil with >40% of area not vegetated; includes mineral licks and bare agricultural fields; natural bare exposed rock is under the rocky outcrop category.
3.3.7	playa (alkaline, saline)	Shallow desert basins without natural drainage-ways where water accumulates and evaporates seasonally.
3.3.8	no correlation	
3.4	snow	Selected features of snow. Can be negative or positive.
3.4.1	snow depth	Any measure of the distance between the top layer of snow and the ground below.
3.4.2	glaciers, snow field	Areas of permanent snow and ice.
3.5	insect fall	The accumulation of dead insects in an aquatic environment. Note: complete this field only for aquatic map units.
3.6	litter fall	The accumulation of dead plant material in an aquatic water environment. Note: complete this field only for aquatic map units.
3.7	precipitation	Accumulation of rainfall and/or snowfall in an aquatic environment. Note: complete this field only for aquatic map
3.8	wind stress	Effects of wind on the turbidity and movement of hydrologic forces. Can influence fish through upwelling of nutrients and mortality of young in turbulent waters. Note: complete this field only for aquatic map units.
4.0	Freshwater Riparian & Aquatic Bodies Habitat Elements	Includes selected forms and characteristics of any body of freshwater.
4.1	Water Characteristics	Various freshwater attributes. Ranges of continuous attributes that are key to the queried species, if known, will be in the comments.
4.1.1	dissolved oxygen	The amount of oxygen passed into solution. Note, only complete this field if you are actually sampling for DO.
4.1.2	water depth	Enter the distance from the surface of the water to the bottom substrate.
4.1.3	dissolved solids	A measure of dissolved minerals in water. Note, only complete this field if you are actually sampling for dissolved
4.1.4	water pH	A measure of water acidity or alkalinity. Note, only complete this field if you are actually sampling for pH.
4.1.5	water temperature	Water temperature range that is key to the queried species, if known, is in the comments field. Note, only complete this field if you are actually sampling water temperature.
4.1.6	water velocity	The speed or momentum of water flow. Note, only complete this field if you are actually sampling water velocity.
4.1.7	water turbidity	Refers to the amount of roiled sediment within the water and the resulting clarity of the water. Note, only complete this field if you are actually sampling for turbidity.
4.1.8	free water (derived from any source)	Water derived from any source
4.1.9	salinity and alkalinity	The presence of salts.
4.1.10	icing in inland rivers and streams (scouring action)	Freezing of water columns and benthic substrate; especially important to fish and invertebrates in small and headwater stream and rivers that may freeze solid. Substrate scouring comes during spring runoff.
4.1.11	metals in water column	A measure of metals present in water.
4.1.12	nutrient enrichment	Enrichment of the water column with nutrients (i.e., decaying salmon carcasses)
4.2	Rivers & Streams	Various characteristics of streams and rivers.
4.2.1	oxbows	A pond or wetland created when a river bend is cut off from the main channel of the river.
4.2.2	order and class	Systems of stream classification.
4.2.2.1	intermittent	Streams/rivers, which contain non-tidal flowing water for only part of the year, water may remain in isolated pools.
4.2.2.2	upper perennial	Streams/rivers with a high gradient, fast water velocity, no tidal influence, some water flowing throughout the year, substrate consists of rock, cobbles, or gravel with occasional patches of sand, little floodplain development.
4.2.2.3	lower perennial	Streams/rivers with a low gradient, slow water velocity, no tidal influence, some water flowing throughout the year, substrate consists mainly of sand and mud, floodplain is well developed.
4.2.3	zone	System of water body classification based on the horizontal strata of the water column.
4.2.3.1	open water	Open water areas not closely associated with the shoreline or bottom.
4.2.3.2	submerged/benthic	Relating to the bottom of a body of water, includes the substrate and the overlaying body of water within one meter of the substrate.
4.2.3.3	shoreline	Continually exposed substrate that is subject to splash, waves, and/or periodic flooding. Includes gravel bars, islands, and immediate nearshore areas.
4.2.4	in-stream substrate	The bottom materials in a body of water.
4.2.4.1	boulders	Rocks (Boulders) > 256 mm (10") in diameter.
4.2.4.2	cobble/gravel	Rocks or pebbles, 4-256 mm in diameter (10"), substrata may consist of cobbles, gravel, shell, and sand with no one substratum type exceeding 70 percent cover.
4.2.4.3	sand/mud	Fine substrata < 4 mm in diameter, little gravel present, may be mixed with organics.
4.2.4.4	bedrock	Reflects bedrock as a substrate in aquatic environs (e.g., stream, river, lake).
4.2.4.5	aquatic bentic structure	Embeddedness, interstitial space

4.2.5	vegetation	Herbaceous plants
4.2.5.1	submergent vegetation	Rooted aquatic plants that do not emerge above the water surface.
4.2.5.2	emergent vegetation	Rooted aquatic plants that emerge above the water surface.
4.2.5.3	floating mats	Unrooted plants that form vegetative masses on the surface of the water.
4.2.6	coarse woody debris in streams and rivers	Any piece of woody material (debris piles, stumps, root wads, fallen trees) that intrudes into or lies within a river or stream.
4.2.6.1	rootwads	Lower stem and root fan of a dead tree.
4.2.6.2	large woody debris (tree stems)	"Large" is considered stems that are 10 cm (4 in) in diameter or larger, and 2 m (6 ft) in length or longer.
4.2.6.3	small woody debris (branches, twigs, etc.)	"Small" is considered stems that are less than 10 cm (4 in) in diameter.
4.2.7	pools	Portions of the stream with reduced current velocity, often with water deeper than surrounding areas.
4.2.7.1	secondary channel pools	formed by merging-flow scour from secondary channels
4.2.7.2	backwater pools	eddy or slack water along the channel margin separated from the main current by a gravel bar or small channel obstruction.
4.2.7.3	trench pools	long, usually deep slot in a stable substrate (often bedrock).
4.2.7.4	plunge pools	basin scoured by a vertical drop over a channel obstruction.
4.2.7.5	lateral scour pools	scoured basin near the channel margin caused by flow being directed to one side of the stream by a partial channel obstruction.
4.2.7.6	dammed pools	Dammed pools: pool impounded upstream from a complete or nearly complete channel blockage (including beaver ponds).
4.2.8	riffles	Shallow rapids where the water flows swiftly over completely or partially submerged obstructions to produce surface agitation, but where standing waves are absent.
4.2.8.1	low gradient riffles	shallow reach of gradient <4% with moderate current velocity and moderate turbulence.
4.2.8.2	rapids	shallow reach of gradient >4% with high current velocity and considerable turbulence.
4.2.8.3	cascades	series of small steps of alternating small waterfalls and small pools.
4.2.9	runs/glides	Areas of swiftly flowing water, without surface agitation or waves, which approximates uniform flow and in which the slope of the water surface is roughly parallel to the overall gradient of the stream reach.
4.2.10	overhanging vegetation	Herbaceous plants that cascade over stream and riverbanks and are < 1 meter above the water surface.
4.2.11	waterfalls	Steep descent of water within a stream or river.
4.2.12	banks	Rising ground that borders a body of water.
4.2.12.1	undercut banks	Stream or river banks that have been undercut by hydrologic forces resulting in the bank overhanging the water. This feature is critical to many fish species for cover from predation.
4.2.13	seeps or springs	A concentrated flow of ground water issuing from openings in the ground.
4.2.14	channel morphology	the general shape of a channel
4.2.14.1	Channel length	a measure of the length of a reach of stream channel
4.2.14.2	Channel width	a measure of the width of a reach of stream channel
4.2.15	flow	Rate of water flow, typically given in cubic feet per second (ft ³ /sec)
4.2.15.1	high flow	Change in interannual variability in high flows.
4.2.15.2	low flow	Change in interannual variability in low flows.
4.2.15.3	diel flow	Intra-daily variation in flow level (regulated rivers influenced by storm water runoff).
4.2.15.4	intra-annual flow	The average extent of intra-annual flow variation during a month (stream "flashiness").
4.3	ephemeral pools	Pools that contain water for only brief periods of time usually associated with periods of high precipitation.
4.4	sand bars	Exposed areas of sand or mud substrate.
4.5	gravel bars	Exposed areas of gravel substrate.
4.6	Lakes/Ponds/Reservoirs	Various characteristics of lakes, ponds, and reservoirs.
4.6.1	zone	System of water body classification based on the horizontal strata of the water column.
4.6.1.1	open water	Open water areas not closely associated with the shoreline or bottom substrates.
4.6.1.2	submerged/benthic	Relating to the bottom of a body of water, includes the substrate and the overlying body of water within one meter of the substrate.
4.6.1.3	shoreline	Continually exposed substrate that is subject to splash, waves, and/or periodic flooding. Includes gravel bars, islands, and immediate nearshore areas.
4.6.2	in-water substrate	The bottom materials in a body of water.
4.6.2.1	boulders	Rocks (Boulders) > 256 mm (10 inches) in diameter.
4.6.2.2	cobble/gravel	Rocks or pebbles, 4-256 mm in diameter (10"), substrata may consist of cobbles, gravel, shell, and sand with no one substratum type exceeding 70 percent cover.
4.6.2.3	sand/mud	Fine substrata < 4 mm in diameter, little gravel present, may be mixed with organics.
4.6.3	vegetation	Herbaceous plants.
4.6.3.1	submergent vegetation	Rooted aquatic plants that do not emerge above the water surface.
4.6.3.2	emergent vegetation	Rooted aquatic plants that emerge above the water surface.
4.6.3.2.1	Sedges and rushes	Emergent vegetation characterized by a predominance of sedges and rushes.
4.6.3.3	floating mats	Unrooted plants that form vegetative masses on the surface of the water.
4.6.3.4	Riparian (including woody vegetation)	Emergent vegetation characterized by a predominance of woody vegetation.
4.6.4	size	Refers to whether or not the species is differentially associated with water bodies based on their size.
4.6.4.1	ponds	< 2 ha
4.6.4.2	lakes	>= 2 ha
4.7	Wetlands/Marshes/Wet Meadows/Bogs and Swamps	Various components and characteristics related to any of these systems.
4.7.1	riverine wetlands	Wetlands found in association with rivers.
4.7.2	context	When checked, indicates that the setting of the wetland, marsh, wet meadow, bog or swamp is key to the queried species.
4.7.2.1	forest	Wetlands within a forest.
4.7.2.2	non-forest	Wetlands that are not surrounded by forest.
4.7.3	size	When checked, indicates that the queried species is differentially associated with a wetland, marsh, wet meadow, bog or swamp based on the size of the water body.
4.7.4	marshes	Frequently or continually inundated wetlands characterized by emergent herbaceous vegetation (grasses, sedges, reeds) adapted to saturated soil conditions.
4.7.5	wet meadows	Grasslands with waterlogged soil near the surface but without standing water for most of the year.
4.8	islands	A piece of land made up of either rock and/or unconsolidated material that projects above and is completely surrounded by water.
4.9	seasonal flooding	Flooding that occurs periodically due to precipitation patterns.
4.10	Littoral zone	Area of shallow water where some fish migrate, find protection and find key food resources. Typically regarded as the shoreline (<5m depth) of lakes, reservoirs, and large rivers.
5.0	Marine Habitat Elements	Selected biotic and abiotic components and characteristics of marine systems.
5.1	zone	System of marine classification based on water depth, and relationship to substrate.

		The zone that extends landward from the higher high water line up to either the top of a coastal cliff or the landward limit of marine process (i.e., storm surge limit).
5.1.1	supratidal	
5.1.2	intertidal	The zone between the higher high water line and the lower low water line.
		The zone that extends from the lower low water line seaward to the 20 meter isobath, typically within 1 kilometer of shore i.e.
5.1.3	nearshore subtidal	
5.1.4	shelf	The area between the 20 and 200-meter isobath, typically within 60 kilometers of shore.
5.1.5	oceanic	The zone that extends seaward from the 200-meter isobath.
5.2	substrates	The bottom materials in a body of water.
5.2.1	bedrock	The solid rock underlying surface materials.
5.2.2	boulders	Large, worn, rocks > 256 mm (10 inches) in diameter.
		Consolidated clays forming a substratum firm enough to support an epibenthos and too firm to support a normal infauna (clams, worms, etc.), but with an unstable surface which sloughs frequently.
5.2.3	hardpan	
5.2.4	cobble	Rocks or pebbles, 64-256 mm in diameter, may be a mix of cobbles, gravel, shells, and sand, with no one type exceeding 70 percent cover.
5.2.5	mixed-coarse	Substrata consisting of cobbles, gravel, shell, and sand with no one substratum type exceeding 70 percent cover.
5.2.6	gravel	Small rocks or pebbles, 4-64 mm in diameter.
5.2.7	sand	Fine substrata < 4 mm in diameter, little gravel present, may be mixed with organics.
5.2.8	mixed-fine	Mixture of sand and mud particles < 4 mm in diameter, little gravel present.
5.2.9	mud	Fine substrata < 0.06 mm in diameter, little gravel present, usually mixed with organics.
5.2.10	organic	Substrata composed primarily of organic matter such as wood chips, leaf litter, or other detritus.
5.2.11	clay	Substrata composed primarily of clayey materials.
5.2.12	shell	Substrata composed of mainly marine organism shells.
5.2.13	Artificial substrata (riprap)	Substrata consisting of artificial (man-made) material including riprap.
5.3	energy	Degree of exposure to oceanic swell, currents, and wind waves.
5.3.1	degree of exposure	Measure of how exposed a shoreline is to the hydrologic forces of a large body of water.
5.3.1.1	Protected	No sea swells, little or no current, and restricted wind fetch.
		Shorelines protected from sea swell, but may receive waves generated by moderate wind fetch, and/or moderate to weak tidal currents.
5.3.1.2	Semi protected	
		Oceanic swell attenuated by offshore reefs, islands, or headlands, but shoreline substantially exposed to wind waves, and/or strong to moderated tidal currents.
5.3.1.3	Partially exposed	
5.3.1.4	Exposed	Highly exposed to oceanic swell, wind waves, and/or very strong currents.
5.3.2	Sources of energy	Hydrodynamic forces in a marine environment.
5.3.2.1	Upwelling	A process in which cold, often nutrient-rich waters from the ocean depths rise to the surface.
5.3.2.2	Local jets and eddies	strong currents moving in different directions from the main current, often in a circular motion in eddies.
5.3.2.3	Outflow plume	pattern of circulation of one body of water flowing into another.
5.3.2.4	Fresh water inflow	area of flow where a freshwater source meets marine waters.
5.4	vegetation	Includes herbaceous plants and plants lacking vascular systems.
5.4.1	species dominated communities	Species dominated communities
5.4.1.1	mixed macro algae	Includes brown, green, and red algae.
5.4.1.1.1	algal blooms	Quickly growing concentrations of algae that may be harmful to the environment, plants, or animals.
5.4.1.1.2	toxic blooms	High concentrations of cyanobacteria that are highly toxic to plants and animals.
5.4.1.2	kelp	Subaquatic rooted vegetation found in the nearshore marine environment.
5.4.1.3	eelgrass	Subaquatic rooted vegetation found in an estuarine environment
5.4.1.4	pickleweed	A salt loving plant (<i>Salicornia europaeae</i>) found in estuarine environments.
5.4.2	vegetation zone	Tidally influenced vegetation zones
5.4.2.1	Low sandy marshes	Occur on sandy substrate with a gradual slope, typically on the low-energy side of bay mouth sand spits or as fringing marshes on islands with coarse-textured sediments. They are flooded by nearly all high tides and drain diffusely (i.e., there are not tidal creeks) over the marsh surface. Near the tidal flat edge, the vegetation is scattered, but becomes continuous up the slope.
5.4.2.2	Low silty marshes	Develop on fine-textured sediments, silt, or mud substrates in low energy parts of estuaries and are relatively flat. These marshes develop in areas of rapid sedimentation and are flooded by nearly all high tides; have diffuse drainage patterns with some defined channels around clumps of plants.
5.4.2.3	Sedge marshes	Form on silt and have a nearly level surface. They are often found on islands or delta edges with elevations somewhat above the first two marsh types. They are flooded by most high tides and drain via creeks in the higher sedge marshes and diffusely in the lower ones.
5.4.2.4	Immature high marshes	Relatively level with some bare depressions and are located on silty substrates. Organic matter accumulation is abundant here as it is in sedge wetlands. Immature high marshes occur above sedge and low sandy marshes, usually at least 40 cm above the tidal flat; often the transition is an abrupt rise. Many of the high tides (especially the higher highs) cover the soil surface. A well-defined system of channels drain and flood these marshes.
5.4.2.5	Mature high marshes	They are level and have developed extensive peaty soils. A dendritic network of steep-sided stream channels circulates water to the soil surface on higher high tides. Shallow saline pools produce openings in the otherwise continuous sward of vegetation. Salinities fluctuate widely and depend on rainfall, tidal input, and evaporation.
5.4.2.6	Bulrush and sedge marshes	Low marshes in brackish parts of the estuary. The substrate is silt or sand, and inundation occurs with most high tides. Drainage is diffuse; vegetation is continuous and its composition is dependent on the salinity.
5.4.2.7	Intertidal gravel marshes	Rare forms; develop on sand and gravel bars near the mouths of relatively high-energy estuaries with large volumes of freshwater. Vegetation is discontinuous and of a type which indicates low salinities. The salt from the tidal water is probably leached by rainwater and freshwater runoff through the coarse substrates.
5.4.2.8	Diked salt marshes	Manmade habitats that develop when the tides are excluded from immature and mature high marshes. Although non-salt marsh plants may invade, the area retains some wetland characteristics due to seepage, high water tables, and perhaps residual salinity. Vegetation is continuous over the marsh surface and the old dendritic stream channels system has collapsed.
5.4.2.9	Riparian zone (freshwater influenced)	Reflects the terrestrial vegetation community immediately alongside marine, estuarine, lagoon, and inlet water environs. This area contributes nutrients, insects (i.e., "insect rains"), minerals, vegetation, soil, and woody stems directly to marine/estuarine systems.
5.4.2.9.1	coniferous	Riparian vegetation community dominated by coniferous forests.
5.4.2.9.2	deciduous	Riparian vegetation community dominated by deciduous forests.
5.4.2.9.3	mixed coniferous/deciduous	Riparian vegetation community dominated by a mixture of coniferous and deciduous forests.
5.4.2.9.4	sedges	Riparian vegetation community dominated by sedges.
5.4.2.9.5	forbs	Riparian vegetation community dominated by forbs.
5.5	water depth	Refers to the vertical layering of the water column.
5.5.1	surface layer	The uppermost part of the water column.
5.5.1.1	fronts (e.g. tide rips, and confluence zones)	A current of water disturbed by an opposing current, especially in tidal water or by passage over an irregular bottom.
5.5.1.2	surface microlayer (neuston)	The thin uppermost layer of the water's surface.

5.5.2	euphotic	Upper layer of a water body that receives sufficient sunlight for the photosynthesis of plants.
5.5.3	disphotic	Area below the euphotic zone where photosynthesis ceases.
5.5.4	demersal/benthic	Submerged lands including vegetated and unvegetated areas.
5.6	water temperature	Measure of ocean water temperature.
5.7	salinity zone	The presence and concentration of salts; salinity range that is key to the species, if it is known, will be in the comments field. Positive or negative influences.
5.7.1	tidal fresh	Tidal freshwater
5.7.2	mixing	Area with recurrent mixing of freshwater and seawater; brackish waters.
5.7.3	seawater	Highly saline water from marine waters.
5.8	forms	Morphological elements within marine areas.
5.8.1	beach	An accumulation of unconsolidated material (sand, gravel, angular fragments) formed by waves and wave-induced currents in the intertidal and subtidal zones.
5.8.2	off-shore islands/rocks/sea stacks/off-shore cliffs	A piece of land made up of either rock and/or unconsolidated material that projects above and is completely surrounded by water at higher high water for large (spring) tide. Includes off-shore marine cliffs.
5.8.3	marine cliffs (mainland)	A sloping face steeper than 20 degrees usually formed by erosional processes and composed of either bedrock and/or unconsolidated materials.
5.8.4	delta	Accumulations of sand, silt, and gravel deposited at the mouth of a stream where it discharges into the sea.
5.8.5	dune	In a marine context; a mound or ridge formed by the transportation and deposition of wind-blown material (sand and occasionally silt).
5.8.6	lagoon	Shallow depression within the shore zone continuously occupied by salt or brackish water lying roughly parallel to the shoreline and separated from the open sea by a barrier.
5.8.7	salt marsh	A coastal wetland area which is periodically inundated by tidal brackish or salt water and which supports significant (15% cover) non-woody vascular vegetation (e.g., grasses, rushes, sedges) for at least part of the year.
5.8.8	reef	A rock outcrop, detached from the shore, with maximum elevations below the high-water line.
5.8.9	tidal flat	A level or gently sloping (less than 5 degrees) constructional surface exposed at low tide, usually consisting primarily of sand or mud with or without detritus, and resulting from tidal processes.
5.8.10	tide pools	Pools of water left behind after tides recede.
5.8.11	high tide current channels	Channels formed by the moment of water at high tides.
5.8.12	complex dendritic channel morphology	Dendritic channel complexity reflects the extensive dissection of the inter-tidal environment; the many naturally-deepened aquatic channels offer important structures providing food and refuge environs (even short-term) for estuarine and marine fishes
5.8.13	spit berms	Berms of sand that are formed on spits due to wave action.
5.8.14	underwater channels	Channels formed by the movement of water, such as at a river or stream mouth on a larger body of water, that are permanently underwater.
5.9	water clarity	As influenced by sediment load.
6.0	No Data	
7.0	Fire as a Habitat Element	Fire can influence species in a positive or negative way.
8.0	Anthropogenic Disturbances and Elements	Anthropogenic - Related Habitat Elements: This section contains selected examples of human-related Habitat Elements that may be a key part of the environment for many species. These HE's may have either a negative or positive influence on the queried species.
8.1	campgrounds/picnic areas	Sites developed and maintained for camping and picnicking.
8.2	roads	Roads that are either paved or unpaved.
8.2.1	paved	Roads that are paved with asphalt or concrete.
8.2.2	un-paved	Roads or trails that are not paved (i.e., gravel or dirt roads).
8.3	buildings	Permanent structures.
8.4	bridges	Permanent structures typically over water or ravines.
8.5	diseases transmitted by domestic animals	Some domestic animal diseases may be a source of mortality or reduced vigor for wild species.
8.6	harvest/persecution (of animals)	Includes illegal harvest/poaching, incidental take (resulting from fishing net by-catch, or by hay mowing, for example), and targeted removal for pest control.
8.7	fences/corrals	Wood, barbed wire, or electric fences.
8.8	supplemental food	Food deliberately provided for wildlife (e.g. bird feeders, ungulate feeding programs, etc.) as well as spilled or waste grain along railroads and cattle feedlots.
8.9	refuse (includes landfills)	Any source of human-derived garbage (includes landfills).
8.10	supplemental boxes, structures and platforms	Includes birdhouses, bat boxes, raptor and waterfowl nesting platforms.
8.11	guzzlers and waterholes	Water sources typically built for domestic animal use.
8.12	toxic chemical use	Proper use of regulated chemicals; documented effects only.
8.12.1	herbicides/fungicides	Chemicals used to kill vegetation and fungi.
8.12.2	insecticides	Chemicals used to kill insects.
8.12.3	pesticides	Chemicals used to kill vertebrate species.
8.12.4	fertilizers	Chemicals used to enhance vegetative growth.
8.12.5	fire fighting chemicals	Chemicals used to suppress fire.
8.13	hedgerows/windbreaks	Woody and/or shrubby vegetation either planted or that develops naturally along fence lines and field borders.
8.14	sewage treatment plant	Settling ponds associated with sewage treatment plants.
8.15	repellents	Various methods purposely used against wildlife species that damage crops or property (excluding pesticides and insecticides)..
8.15.1	chemical (taste or smell)	Chemical substances that repel wildlife.
8.15.2	noise or visual disturbance	Non-chemical methods to deter wildlife.
8.16	culverts	Drain crossings under roads or railroads.
8.17	irrigation ditches/canals	Ditches built to transport water to agricultural crops or to handle runoff.
8.18	powerlines/corridors	Utility lines, poles, and rights-of-way associated with transmission, telephone, and gas lines.
8.19	pollution	Human-caused environmental contamination.
8.19.1	chemical	Contamination caused by chemicals.
8.19.2	sewage	Contamination caused by human waste.
8.19.3	water	Aquatic contamination from any source.
8.20	piers	A structure built out over water.
8.21	mooring piles, dolphins, buoys	Floating objects anchored out in the water for nautical purposes.
8.22	bulkheads, seawalls, revetment	Retaining structures built to protect the shoreline from wave action.
8.23	jetties, groins, breakwaters	Structures built to influence the current or protect harbors.
8.24	water diversion structures	Structures built to funnel or direct water, including dams, dikes and levies.
8.25	log boom	A raft of logs lashed together either to transport the logs or as barriers to boat traffic near marinas or dams.
8.26	boats/ships	Watercraft, either motorized or non-motorized.
8.27	dredge spoil islands	Sediment deposited from dredging operations.

8.28	hatchery facilities and fish	Fish that are hatched in captivity and later released into the wild. For simplicity this refers to freshwater areas, though marine birds and mammals likely feed on hatchery-released fish too.
8.29	hydrologic regime - regulated (river)	Rivers that are altered and controlled by human activities.
8.30	obstructions (to fish passage)	Obstructions or blockages to fish passage (e.g., poorly situated culverts; fences; piers; warm thermal pulses).
8.31	weirs	A fence or wattle placed in a stream to catch or retain fish.
8.32	other	Any other anthropogenic-related habitat elements not described by KECs 8.1-8.31)

Master List Key Ecological Functions (KEFs)

SHP-KEF	KEFDescription
~	added by fish review
1	Trophic relationships
1.1	heterotrophic consumer
1.1.1	primary consumer (herbivore) (also see below under Herbivory)
1.1.1.1	foliovore (leaf-eater)
1.1.1.2	spermivore (seed-eater)
1.1.1.3	browser (leaf, stem eater)
1.1.1.4	grazer (grass, forb eater)
1.1.1.5	frugivore (fruit-eater)
1.1.1.6	sap feeder
1.1.1.7	root feeders
1.1.1.8	nectivore (nectar feeder)
1.1.1.9	fungivore (fungus feeder)
1.1.1.10	flower/bud/catkin feeder
1.1.1.11	aquatic herbivore
1.1.1.12	feeds in water on decomposing benthic substrate
1.1.1.13	bark/cambium/bole feeder
1.1.1.14	periphyton eater (including algae) ~
1.1.1.15	phytoplankton eater (including algae) ~
1.1.2	secondary consumer (primary predator or primary carnivore)
1.1.2.1	invertebrate eater
1.1.2.1.1	terrestrial invertebrates
1.1.2.1.2	aquatic macroinvertebrates
1.1.2.1.3	freshwater or marine zooplankton
1.1.2.2	vertebrate eater (consumer or predator of herbivorous vertebrates)
1.1.2.2.1	piscivorous (fish eater)
1.1.2.3	ovivorous (egg eater)
1.1.2.4	prey (fish) for secondary consumers ~
1.1.3	tertiary consumer (secondary predator or secondary carnivore)
1.1.4	carrion feeder
1.1.5	cannibalistic
1.1.6	coprophagous (feeds on fecal material)
1.1.7.1	aquatic (e.g. offal and bycatch of fishing boats)
1.1.7.2	terrestrial (e.g. landfills)
1.1.7	feeds on human garbage/refuse
1.2	prey relationships
1.2.1	prey for secondary or tertiary consumer (primary or secondary predator)
1.2.2	fish prey for secondary or tertiary consumer (primary or secondary predator)
2	aids in physical transfer of substances for nutrient cycling (C,N,P, etc.)
2.1	significant carrier of nutrients ~
2.1.1	within aquatic system ~
2.1.2	within terrestrial systems (including wetlands) ~
2.2	significant carrier of heavy metals ~
2.2.1	within aquatic systems ~
2.2.2	within terrestrial systems (including wetlands) ~
3	organismal relationships
3.1	controls or depresses insect population peaks
3.1.1	influences aquatic invertebrate population peaks ~
3.1.2	influences zooplankton population peaks ~
3.2	controls terrestrial vertebrate populations (through predation or displacement)
3.3	pollination vector
3.4	transportation of viable seeds, spores, plants or animals ^
3.4.1	disperses fungi

3.4.2	disperses lichens
3.4.3	disperses bryophytes, including mosses
3.4.4	disperses insects and other invertebrates
3.4.4.1	disperse aquatic invertebrates ~
3.4.5	disperses seeds/fruits (through ingestion or caching)
3.4.6	disperses vascular plants
3.5.1	creates feeding opportunities (other than direct prey relations)
3.5.1.1	creates sapwells in trees
3.5.2	creates roosting, denning, or nesting opportunities
3.5	creates feeding, roosting, denning, or nesting opportunities for other organisms
3.6.1	aerial structures
3.6.2	ground structures
3.6.3	aquatic structures
3.6	primary creation of structures (possibly used by other organisms)
3.7.1	aerial structures
3.7.2	ground structures
3.7.3	aquatic structures
3.7	user of structures created by other species
3.8.1	interspecies parasite
3.8.2	common interspecific host
3.8	nest parasite
3.9	primary cavity excavator (in aquatic and/or terrestrial systems)
3.10	secondary cavity user
3.11.1	creates large burrows (rabbit-sized or larger)
3.11.2	creates small burrows (less than rabbit-sized)
3.11	primary burrow excavator (fossorial or underground burrows)
3.12	uses burrows dug by other species (secondary burrow user)
3.13	creates runways (possibly used by other species)
3.14	uses runways created by other species)
3.15	pirates food from other species
3.16	interspecific hybridization
3.16.1	interspecific hybridization with native species
3.16.2	interspecific hybridization with exotic species
4	carrier, transmitter, or reservoir of vertebrate diseases
4.1	diseases that affect humans
4.2	diseases that affect domestic animals
4.3	diseases that affect other wildlife species
4.4	diseases that affect other fish species ~
5	soil relationships
5.1	physically affects (improves) soil structure, aeration (typically by digging)
5.2	physically affects (degrades) soil structure, aeration (typically by trampling)
5.3	physically affects aquatic soils and bed materials (typically by digging or spawning actions)
6	wood structure relationships (either living or dead wood)
6.1	physically fragments down wood
6.2	physically fragments standing wood
7	water relationships
7.1	impounds water by creating diversions or dams
7.2	creates ponds or wetlands through wallowing
8	vegetation structure and composition relationships
8.1	creates standing dead trees (snags)
8.2	herbivory on trees or shrubs that may alter vegetation structure and composition (browsers)
8.3	herbivory on grasses or forbs that may alter vegetation structure and composition (grazers)

Study Area - Species - Potential List

Largemouth bass	<i>Micropterus salmoides</i>	Black-necked Stilt	<i>Himantopus mexicanus</i>	Bewick's Wren	<i>Thryomanes bewickii</i>	Lawrence's Goldfinch	<i>Carduelis lawrencei</i>
Black bullhead	<i>Ictalurus (Ameiurus) melas</i>	Greater Yellowlegs	<i>Tringa melanoleuca</i>	House Wren	<i>Troglodytes aedon</i>	American Goldfinch	<i>Carduelis tristis</i>
Carp	<i>Cyprinus carpio</i>	Lesser Yellowlegs	<i>Tringa flavipes</i>	Ruby-crowned Kinglet	<i>Regulus calendula</i>	House Sparrow	<i>Passer domesticus</i>
Mosquitofish	<i>Gambusia affinis</i>	Spotted Sandpiper	<i>Actitis macularia</i>	Blue-gray Gnatcatcher	<i>Poliopitla caerulea</i>	Virginia opossum	<i>Didelphis virginiana</i>
Green sunfish	<i>Lepomis cyanellus</i>	Western sandpiper	<i>Calidris mauri</i>	Swainson's Thrush	<i>Sialia mexicana</i>	California Myotis	<i>Myotis californicus</i>
Tilapia	<i>Oreochromis spp.</i>	Least Sandpiper	<i>Calidris minutilla</i>	Hermit Thrush	<i>Catharus ustulatus</i>	Yuma Myotis	<i>Myotis yumanensis</i>
Western toad	<i>Bufo boreas</i>	Wilson's Snipe	<i>Gallinago delicata</i>	American Robin	<i>Turdus migratorius</i>		<i>Lasionycteris</i>
California Treefrog	<i>Pseudacris regilla</i>	Ring-billed Gull	<i>Larus delawarensis</i>	Wrentit	<i>Chamaea fasciata</i>	Silver-haired Bat	<i>noctivagans</i>
Bullfrog	<i>Rana catesbeiana</i>	California Gull	<i>Larus californicus</i>	Northern mockingbird	<i>Mimus polyglottos</i>	Western Pipistrelle	<i>Pipistrellus hesperus</i>
Red-eared Slider	<i>Trachemys scripta elegans</i>	Caspian Gull	<i>Larus occidentalis</i>	California Thrasher	<i>Toxostoma redivivum</i>	Big Brown Bat	<i>Eptesicus fuscus</i>
Southern Alligator Lizard	<i>Elgaria multicarinata</i>	Rock Pigeon	<i>Columba livia</i>	European Starling	<i>Sturnus vulgaris</i>	Western Red Bat	<i>Lasiurus blossevillei</i>
Western Fence Lizard	<i>Sceloporus occidentalis</i>	Mourning Dove	<i>Zenaida macroura</i>	American Pipit	<i>Anthus rubescens</i>	Hoary Bat	<i>Lasiurus cinereus</i>
Side-blotched lizard	<i>Uta stansburiana</i>	Barn Owl	<i>Tyto alba</i>	Cedar Waxwing	<i>Bombycilla cedrorum</i>	Townsend's Big-eared Bat	<i>Corynorhinus townsendii</i>
Two-Striped Garter Snake	<i>Thamnophis hammondi</i>	Great Horned Owl	<i>Bubo virginianus</i>	Phainopepla	<i>Phainopepla nitens</i>		
Pied-billed Grebe	<i>Podilymbus podiceps</i>	Vaux's Swift	<i>Chaetura vauxi</i>	Orange-crowned Warbler	<i>Vermivora celata</i>		
Eared Grebe	<i>Podiceps nigricollis</i>	White-throated Swift	<i>Aeronautes saxatalis</i>	Nashville Warbler	<i>Vermivora ruficapilla</i>	Brazilian Free-tailed Bat	<i>Tadarida brasiliensis</i>
Double-crested Cormorant	<i>Phalacrocorax auritus</i>	Black-chinned Hummingbird	<i>Archilochus alexandri</i>	Yellow Warbler	<i>Dendroica coronata</i>	Desert Cottontail	<i>Sylvilagus audubonii</i>
Great blue heron	<i>Ardea herodias</i>	Anna's Hummingbird	<i>Calypte anna</i>	Black-throated Gray Warbler	<i>Dendroica nigrescens</i>	California ground squirrel	<i>Spermophilus beecheyi</i>
Great Egret	<i>Ardea alba</i>	Rufous Hummingbird	<i>Selasphorus rufus</i>	Townsend's Warbler	<i>Dendroica townsendi</i>	Eastern Fox Squirrel	<i>Sciurus niger</i>
Snowy Egret	<i>Egretta thula</i>	Allen's Hummingbird	<i>Selasphorus sasin</i>	Hermit Warbler	<i>Dendroica occidentalis</i>		
Green Heron	<i>Butorides virescens</i>	Belted Kingfisher	<i>Ceryle alcyon</i>	MacGillivray's Warbler	<i>Oporornis tolmiei</i>		
Black-crowned Night-Heron	<i>Nycticorax nycticorax</i>	Acom Woodpecker	<i>Melanerpes formicivorus</i>	Common Yellowthroat	<i>Geothlypis trichas</i>	Little Pocket Mouse	<i>Perognathus longimembris</i>
Turkey Vulture	<i>Cathartex aura</i>	Red-breasted Sapsucker	<i>Sphyrapicus ruber</i>	Wilson's Warbler	<i>Wilsonia pusilla</i>	Western Harvest Mouse	<i>Reithrodontomys megalotis</i>
Canada Goose	<i>Branta canadensis</i>	Nuttall's Woodpecker	<i>Picoides nuttallii</i>	Yellow-breasted Chat	<i>Icteria virens</i>		
Gadwall	<i>Anas strepera</i>	Downy Woodpecker	<i>Picoides pubescens</i>	Western Tanager	<i>Piranga ludoviciana</i>		
American Wigeon	<i>Anas americana</i>	Northern Flicker	<i>Colaptes auratus</i>	Spotted Towhee	<i>Pipilo maculatus</i>		
Mallard	<i>Anas platyrhynchos</i>	Western Wood-pewee	<i>Contopus sordidulus</i>	California Towhee	<i>Pipilo crissalis</i>	Deer Mouse	<i>Peromyscus maniculatus</i>
Blue-winged Teal	<i>Anas discors</i>	Willow Flycatcher	<i>Empidonax traillii</i>	Chipping Sparrow	<i>Spizella passerina</i>	Dusky-footed Wood Rat	<i>Neotoma fuscipes</i>
Cinnamon teal	<i>Anas cyanoptera</i>	Pacific-slope Flycatcher	<i>Empidonax difficilis</i>	Lark Sparrow	<i>Chondestes grammacus</i>	Black Rat	<i>Rattus rattus</i>
Northern Shoveler	<i>Anas clypeata</i>	Black Phoebe	<i>Sayornis nigricans</i>	Savannah Sparrow	<i>Passerculus sandwichensis</i>	Norway Rat	<i>Rattus norvegicus</i>
Northern Pintail	<i>Anas acuta</i>	Say's Phoebe	<i>Sayornis saya</i>	Song sparrow	<i>Melospiza melodia</i>	House Mouse	<i>Mus musculus</i>
Green-winged Teal	<i>Anas crecca</i>	Ash-throated Flycatcher	<i>Myiarchus cinerascens</i>	Lincoln's Sparrow	<i>Melospiza lincolni</i>	Coyote	<i>Canis latrans</i>
Bufflehead	<i>Bucephala albeola</i>	Cassin's Kingbird	<i>Tyrannus vociferans</i>	White-crowned Sparrow	<i>Zonotrichia leucophrys</i>	Raccoon	<i>Procyon lotor</i>
Hooded Merganser	<i>Lophodytes cucullatus</i>	Western Kingbird	<i>Tyrannus verticalis</i>	Golden-crowned Sparrow	<i>Zonotrichia atricapilla</i>	Striped skunk	<i>Mephitis mephitis</i>
Ruddy Duck	<i>Oxyura jamaicensis</i>	Loggerhead Shrike	<i>Lanius ludovicianus</i>	Dark-eyed Junco	<i>Junco hyemalis</i>	Bobcat	<i>Lynx rufus</i>
Muscovy Duck	<i>Cairina moschata</i>	Bell's Vireo	<i>Vireo bellii</i>		<i>Pheucticus melanocephalus</i>		
Osprey	<i>Pandion haliaetus</i>	Cassin's Vireo	<i>Vireo cassinii</i>		<i>Guiraca caerulea</i>		
White-tailed Kite	<i>Elanus leucurus</i>	Hutton's Vireo	<i>Vireo huttoni</i>	Black-headed Grosbeak	<i>Passerina amoena</i>	Amazon sailfin catfish	<i>Pterygoplichthys pardalis</i>
Sharp-shinned Hawk	<i>Accipiter striatus</i>	Warbling Vireo	<i>Vireo gilvus</i>	Blue Grosbeak	<i>Agelaius phoeniceus</i>	African clawed frog	<i>Xenopus laevis</i>
Cooper's Hawk	<i>Accipiter cooperii</i>	Western Scrub Jay	<i>Aphelocoma californica</i>	Lazuli Bunting	<i>Sturnella neglecta</i>	Gopher snake	<i>Pituophis catenifer</i>
Red-shouldered Hawk	<i>Buteo lineatus</i>	American Crow	<i>Corvus brachyrhynchos</i>	Red-winged blackbird	<i>Euphagus cyanocephalus</i>		
Red-tailed Hawk	<i>Buteo jamaicensis</i>	Common Raven	<i>Corvus corax</i>	Western Meadowlark	<i>Quiscalus mexicanus</i>		
American Kestrel	<i>Falco sparverius</i>	Tree Swallow	<i>Tachycineta bicolor</i>	Brewer's Blackbird	<i>Molothrus ater</i>		
Merlin	<i>Falco columbarius</i>	Violet-green Swallow	<i>Tachycineta thalassina</i>	Great tailed Grackle	<i>Icterus cucullatus</i>		
Peregrine Falcon	<i>Falco peregrinus</i>	Northern rough winged swallow		Brown-headed Cowbird	<i>Icterus bullockii</i>		
Sora	<i>Porzana carolina</i>	Cliff Swallow	<i>Stelgidopteryx serripennis</i>	Hooded Oriole	<i>Carpodacus purpureus</i>		
Common Moorhen	<i>Gallinula chloropus</i>	Barn Swallow	<i>Petrochelidon pyrrhonota</i>	Bullock's Oriole	<i>Carpodacus mexicanus</i>		
American Coot	<i>Fulca americana</i>	Oak Titmouse	<i>Hirundo rustica</i>	Purple Finch	<i>Carduelis psaltria</i>		
Killdeer	<i>Charadrius vociferus</i>	Bushtit	<i>Baeolophus inornatus</i>	House Finch			
			<i>Psaltirparus minimus</i>	Lesser Goldfinch

Relationship Matrix Descriptions
HU Calculation Overview

Relationship Matrix Descriptions

MATRIX 1: Potential Species by Function (KEF) Matrix

The potential species list generated by IBIS is aligned with Key Ecological Functions (KEFs) that could potentially be performed in the habitat type and structural condition represented by the polygon. For example, if the polygon represents a “shrub-steppe” habitat type, the KEFs thought to be performed in that habitat type by the potential species are included in the relationship matrix. This information is acquired from IBIS. The result of this matrix is the number of potential species performing key functions in that habitat type. Example follows:

Lowland Mixed Conifer <u>Habitat Type</u> (Potential)	Function 1 Transportation of Viable Seeds, Spores or Plants	Function 2 Breaks up Down Wood	Function 3 Primary Excavator	Function 4 Eats Terrestrial Invertebrates
American Beaver	1			
Pileated Woodpecker		1	1	1
Black Bear	1	1	1	1
Black-tailed Deer	1	1		
Steelhead Salmon	1			1

Relationship Matrix Descriptions

MATRIX 2: Habitat (Actual KEC) by Function (KEF) Matrix

In this matrix, the functions, or KEFs, are again related to Key Environmental Correlates (KECs), but this time the KECs are those actually present at the site (based on field data inventory). Because this is an actual account, those KEFs not correlated to an actual KEC are then removed. The result of this matrix is the number of KEFs characterized by KECs specific to that polygon. Example follows:

Lowland Mixed Conifer Habitat Type (Actual)	Function 1 Creates Snags	Function 2 Breaks up Down Wood	Function 3 Pollination Vector	Function 4 Primary Excavator	Function 5 Filtering Water	Function 6 Eats Terrestrial Insects
Down Wood		1				1
Snags	1			1		1
Tree Cavities	1	1		1		1
Hollow Living Trees		1				1
Flowers			1			
Emergent Vegetation					1	

Calculations

For Each Matrix

Divide: **total number of 1s in matrix**

total number of non-zero functions*

1

Total # of 1s = 12

Total # non-zero fxns = 4

2

Total # of 1s = 13

Total # non-zero fxns = 6

$$\begin{array}{l} \text{Number of species} \\ \text{performing functions} \end{array} = \frac{12}{4} = 3.0 + \frac{\begin{array}{l} \text{Number of KECs} \\ \text{at site} \end{array}}{\begin{array}{l} \text{Total number of} \\ \text{functions characterized} \end{array}} = \frac{13}{6} = 2.17$$

Per-Acre
Habitat Value
5.17

*non-zero functions refer to function columns in the matrix that have at least one "1" in that column

Introduction

Northwest Habitat Institute (NHI) staff evaluated habitat quality on and along selected portions of the Los Angeles River (LAR) within the city limits of Los Angeles, California in late March and early April 2010. NHI staff used Combined Habitat Assessment Protocols (CHAP) to assess habitat quality.

CHAP methodology includes delineating and displayed habitat types, structural conditions, and attributes as Geographic Information System (GIS) data, which is verified in the field with ocular observations and measured verification transects. Ocular observations and verification transect data is then used to modify initial habitat quality/attribute estimates.

Funding for the LAR habitat assessment project and assistance with data collection was provided by the US Army Corps of Engineers (USACOE). This report includes only the results of the verification transects.

Study Area

The study area is located on the south side of Burbank, California just east of Universal City and includes the Los Angeles River channel and adjacent uplands. The general project area is shown in Figure 1. CHAP verification transects were limited to “soft bottom” areas in the LA River channel and the “Head Works” area.

Figure 1 General location of LA River CHAP study

Verification Transect Locations

Habitat variable data was collected on 11 transects to verify and support GIS map layers and associated ocular habitat attribute estimates. Seven verification transects were established at the Head Works location (Figure 2) while four transects were disbursed in “soft bottom” areas of the LA River (Figure 3 and Figure 4). A transect overview map is shown in Figure 5.

Figure 2 Head Works transect start point locations

Figure 3 LA River riparian transect start point locations (north)

Figure 4 LA River riparian transect start point locations (south)

Figure 5 Verification transect start point overview map (all transect start locations)

Transect start points were established at random locations. Transect azimuths were selected from a random numbers table whenever possible (the narrow, linear nature of riparian habitats/transects precluded use of random azimuths). Once an azimuth was determined, a 300' measuring tape was used as the transect line from which habitat variable measurements were taken.

Transect start and end UTM coordinates were recorded on a Garmin 60CSx® global positioning system (GPS) and are displayed Table 1. The end point for transect 24-1 was unavailable due to limited GPS satellite coverage.

Transect length was 300 feet wherever possible. Transect 19-1, however, was only 250 feet in length because of the limited amount of riparian forest habitat available. Similarly, transect 63-1 extended only 150 feet.

Methods

Verification transects (n = 11) were established in riparian forest, floodplain riparian shrub, grassland, and shrubland cover types located on LA River “soft bottom” sites and/or the Head Works area. Ashley (2010) describes the specific methods used to measure habitat attributes in [Habitat Measurement Techniques](#).

Habitat attributes measured in this study included:

1. Tree and shrub species
2. Tree and shrub canopy cover
3. Tree and shrub height
4. Diameter breast height (DBH)
5. Snag density, size, and class (only one snag was detected)
6. Percent herbaceous plant cover
7. Herbaceous cover height
8. Percent grass cover
9. Percent cover forbs
10. Percent cover exotic/invasive herbaceous vegetation

Tree and shrub data was collected using the point intercept method. Tree canopy point cover was collected at five foot intervals while shrub point intercept data was collected at either five foot or two intervals foot intervals predicated on initial shrub cover estimates (two foot intervals are applied when estimated shrub cover is < 30%).

A rectangular 0.10m² quadrat was used to estimate total herbaceous cover, grass cover, forbs cover, and percent cover of invasive herbaceous species (percent cover = aerial cover). Quadrats were placed adjacent to the transect line at 25 foot intervals. Herbaceous vegetation height measurements were taken within the quadrats with a “pocket rod” and recorded in 10ths of feet (Ashley 2010).

Results

Verification transect results for the LA River and Head Works sites are summarized below. Percent cover estimates are rounded to the nearest whole number. Actual data sets, including species information, can be viewed at the data link locations included in the summary tables. Transect photographs are shown in Appendix A.

LA River

Three verification transects were established in the riparian forest cover type, one transect in shrub-scrub floodplain, and one transect in disturbed grassland. Snag, shrub, and tree data was collected on the riparian forest and shrub-scrub transects (only one snag was detected which had an 8.5 inch dbh). Only herbaceous habitat attribute data was recorded on Transect 63-1 (shrubs were not present).

Tree canopy cover ranged from 17% to 77%. The average minimum tree height was just over 17 feet while the maximum tree height was slightly more than 49 feet. Tree species detected included

eucalyptus (*Eucalyptus globules*), shamel ash (*Fraxinus uhdei*), white mulberry (*Morus alba*), sycamore (*Paltanus* sp.), and red willow (*Salix laevigata*).

Shrub cover ranged from 48% to 64% while mean shrub height varied little extending from approximately 3.5 feet to just over 4 feet. Shrub species (included trees < 16 feet in height) detected included castor bean (*Ricinus* spp.), Mexican fan palm (*Washingtonia robusta*), arroya willow (*Salix lasiolepis*), shamel ash, white mulberry, mule fat (*Baccharis salicifolia*), red willow, and California sagebrush (*Artemisia californica*).

Total herbaceous cover on transect 63-1 was 81%, which was comprised entirely of invasive plant species. Summarized LA River transect results and data spreadsheet links are provided in Table 2.

Table 2 Summarized LA River verification transect results and data links

Cover Type	Transect Number	Habitat Stratum	Percent Cover	Mean Height (Feet)		DBH Class Range (Inches)		Data Link
Riparian Forest	19-1	Trees	58%	49.20		<4 to >20		19
		Shrubs	64%	3.53		N/A		
Riparian Forest	20-1	Trees	72%	37.50		4 to 20		20
		Shrubs	50%	3.77		N/A		
Riparian Forest	24-1	Trees	77%	38.00		4 to >20		24
		Shrubs	53%	4.22		N/A		
Shrub-scrub Floodplain	31-1	Trees	17%	17.30		<4 to 20		31
		Shrubs	48%	4.00		N/A		
Cover Type	Transect Number	Habitat Stratum	Percent Herb. Cover	Mean Height	Percent Grass	Percent Forbs	Percent Exotics	Data Link
Disturbed Grassland	63-1	Herbaceous Stratum	81%	6"	71.50	23.50	80.50	63

Head Works

Four shrubland and two grassland verification transects were established at the Head Works site. Both shrub and herbaceous habitat attribute data was collected on most transects.

Percent shrub cover ranged from 11% to 92% while shrub height was between 5 feet and 6 feet on three transects and just over 10 feet on the fourth transect. Shrub species detected included Spanish broom (*Spartium junceum*), poison oak (*Toxicodendron diversilobum*), mule fat, Mexican elderberry (*Sambucus mexicana*), laurel sumac (*Malosma laurina*), coyote brush (*Baccharis pilularis*), deerweed (*Lotus scoparius*) (half shrub), and California sagebrush (Table 3).

Table 3 Head Works site shrub verification transect results

Cover Type	Transect Number	Habitat Stratum	Percent Cover	Mean Height (Feet)	Data Link
Shrubland	14B-1	Shrubs	11%	5.82	14B-1
Shrubland	14D-1	Shrubs	35%	5.04	14D-1
Riparian Shrub	14F-1	Shrubs	53%	5.75	14F-1
Shrubland	15-1	Shrubs	92%	10.22	15-1

Percent cover of herbaceous vegetation ranged from 67% to 88% with only a trace amount (<1%) comprised of native species while the average height ranged from four to 15 inches. Herbaceous transect results are summarized in Table 4.

Table 4 Head Works site herbaceous stratum verification transect results

Cover Type	Transect Number	Habitat Stratum	Percent Herb. Cover	Mean Height	Percent Grass	Percent Forbs	Percent Exotics	Data Link
Shrubland	14B-1	Herbaceous	67%	4"	31%	50%	67%	14B-1
Grassland	14-1	Herbaceous	84%	13"	82%	5%	83%	14-1
Shrubland	14D-1	Herbaceous	88%	7"	79%	36%	88%	14D-1
Grassland	14G-1	Herbaceous	70%	15"	35%	60%	70%	14G-1
